

ON THE LEADING TERM OF THE EIGENVALUE VARIATION FOR AHARONOV-BOHM OPERATORS WITH A MOVING POLE

LAURA ABATANGELO, VERONICA FELLI

ABSTRACT. We study the behavior of eigenvalues for magnetic Aharonov-Bohm operators with half-integer circulation and Dirichlet boundary conditions in a planar domain. We analyse the leading term in the Taylor expansion of the eigenvalue function as the pole moves in the interior of the domain, proving that it is a harmonic homogeneous polynomial and detecting its exact coefficients.

1. INTRODUCTION

Completing the analysis performed in [1], we deepen the investigation of the behavior of eigenvalues for the magnetic Aharonov-Bohm operator with half-integer circulation and Dirichlet boundary conditions in a planar domain. We refer to [1], [2], [7], and [8] for motivations and references to previous related literature.

For every $a = (a_1, a_2) \in \mathbb{R}^2$, the Aharonov-Bohm vector potential with pole a and circulation $1/2$ is defined as

$$A_a(x_1, x_2) = \frac{1}{2} \left(\frac{-(x_2 - a_2)}{(x_1 - a_1)^2 + (x_2 - a_2)^2}, \frac{x_1 - a_1}{(x_1 - a_1)^2 + (x_2 - a_2)^2} \right), \quad (x_1, x_2) \in \mathbb{R}^2 \setminus \{a\}.$$

Let $\Omega \subset \mathbb{R}^2$ be a bounded, open and simply connected domain containing the origin. For every $a \in \Omega$, we introduce the functional space $H^{1,a}(\Omega, \mathbb{C})$ as the completion of

$$\{u \in H^1(\Omega, \mathbb{C}) \cap C^\infty(\Omega, \mathbb{C}) : u \text{ vanishes in a neighborhood of } a\}$$

with respect to the norm

$$\|u\|_{H^{1,a}(\Omega, \mathbb{C})} = \left(\|\nabla u\|_{L^2(\Omega, \mathbb{C}^2)}^2 + \|u\|_{L^2(\Omega, \mathbb{C})}^2 + \left\| \frac{u}{|x-a|} \right\|_{L^2(\Omega, \mathbb{C})}^2 \right)^{1/2},$$

which, in view of the Hardy type inequality proved in [5] (see also [3, Lemma 3.1 and Remark 3.2]), is equivalent to the norm

$$\left(\|(i\nabla + A_a)u\|_{L^2(\Omega, \mathbb{C}^2)}^2 + \|u\|_{L^2(\Omega, \mathbb{C})}^2 \right)^{1/2}.$$

We denote as $H_0^{1,a}(\Omega, \mathbb{C})$ the space obtained as the completion of $C_c^\infty(\Omega \setminus \{a\}, \mathbb{C})$ with respect to the norm $\|\cdot\|_{H_a^1(\Omega, \mathbb{C})}$.

Keywords. Magnetic Schr dinger operators, Aharonov-Bohm potential, asymptotics of eigenvalues, blow-up analysis.

For every $a \in \Omega$, we say that $\lambda \in \mathbb{R}$ is an eigenvalue of the problem

$$(E_a) \quad \begin{cases} (i\nabla + A_a)^2 u = \lambda u, & \text{in } \Omega, \\ u = 0, & \text{on } \partial\Omega, \end{cases}$$

in a weak sense if there exists $u \in H_0^{1,a}(\Omega, \mathbb{C}) \setminus \{0\}$ (called eigenfunction) such that

$$\int_{\Omega} (i\nabla u + A_a u) \cdot \overline{(i\nabla v + A_a v)} dx = \lambda \int_{\Omega} u \bar{v} dx \quad \text{for all } v \in H_0^{1,a}(\Omega, \mathbb{C}).$$

From classical spectral theory, the eigenvalue problem (E_a) admits a sequence of real diverging eigenvalues $\{\lambda_k^a\}_{k \geq 1}$ with finite multiplicity; in the enumeration $\lambda_1^a \leq \lambda_2^a \leq \dots \leq \lambda_j^a \leq \dots$ each eigenvalue is repeated as many times as its multiplicity. We are interested in the behavior of the function $a \mapsto \lambda_j^a$ in a neighborhood of a fixed point $b \in \Omega$; without loss of generality, we can consider $b = 0 \in \Omega$.

Let us assume that there exists $n_0 \geq 1$ such that

$$(1) \quad \lambda_{n_0}^0 \quad \text{is simple,}$$

and denote

$$\lambda_0 = \lambda_{n_0}^0$$

and, for any $a \in \Omega$,

$$\lambda_a = \lambda_{n_0}^a.$$

In [6, Theorem 1.3] it is proved that, for all $j \geq 1$ such that assumption (1) holds true, the function $a \mapsto \lambda_j^a$ is analytic in a neighborhood of 0. In particular $a \mapsto \lambda_j^a$ is continuous and, if $a \rightarrow 0$, then

$$(2) \quad \lambda_a \rightarrow \lambda_0.$$

Let $\varphi_0 \in H_0^{1,0}(\Omega, \mathbb{C}) \setminus \{0\}$ be a $L^2(\Omega, \mathbb{C})$ -normalized eigenfunction of problem (E_0) associated to the eigenvalue $\lambda_0 = \lambda_{n_0}^0$, i.e. satisfying

$$(3) \quad \begin{cases} (i\nabla + A_0)^2 \varphi_0 = \lambda_0 \varphi_0, & \text{in } \Omega, \\ \varphi_0 = 0, & \text{on } \partial\Omega, \\ \int_{\Omega} |\varphi_0(x)|^2 dx = 1. \end{cases}$$

From [3, Theorem 1.3] (see also [8, Theorem 1.5] and [1, Proposition 2.1]) it is known that

$$(4) \quad \varphi_0 \text{ has at } 0 \text{ a zero of order } \frac{k}{2} \text{ for some odd } k \in \mathbb{N},$$

and there exist $\beta_1, \beta_2 \in \mathbb{C}$ such that $(\beta_1, \beta_2) \neq (0, 0)$ and

$$(5) \quad r^{-k/2} \varphi_0(r(\cos t, \sin t)) \rightarrow \beta_1 \frac{e^{i\frac{t}{2}}}{\sqrt{\pi}} \cos\left(\frac{k}{2}t\right) + \beta_2 \frac{e^{i\frac{t}{2}}}{\sqrt{\pi}} \sin\left(\frac{k}{2}t\right) \quad \text{in } C^{1,\tau}([0, 2\pi], \mathbb{C})$$

as $r \rightarrow 0^+$ for any $\tau \in (0, 1)$. We recall that, by [4] (see also [2, Lemma 2.3]), the function $e^{-i\frac{t}{2}} \varphi_0(r(\cos t, \sin t))$ is a multiple of a real-valued function and therefore either $\beta_1 = 0$ or $\frac{\beta_2}{\beta_1}$ is real. Then φ_0 has exactly k nodal lines meeting at 0 and dividing the whole angle into k equal parts; such nodal lines are tangent to the k half-lines $\{(t, \tan(\alpha_0 + j\frac{2\pi}{k})t) : t > 0\}$, $j = 0, 1, \dots, k-1$, where

$$(6) \quad \alpha_0 = \begin{cases} \frac{2}{k} \operatorname{arccot}\left(-\frac{\beta_2}{\beta_1}\right), & \text{if } \beta_1 \neq 0, \\ 0, & \text{if } \beta_1 = 0. \end{cases}$$

At a deeper study, the rate of convergence of λ_a to λ_0 is strictly related to the number of nodal lines of φ_0 ending at 0. First results in this direction are proved in [2], in which the authors provide some estimates for the rate of convergence (2). A significant improvement of these studies is obtained in [1], where sharp asymptotic behavior of eigenvalues is provided as the pole is approaching an internal zero of an eigenfunction φ_0 of the limiting problem (3) along the half-line tangent to any nodal line of φ_0 ; more precisely, in [1, Theorem 1.2] it is proved that, under assumptions (1) and (4), the limit

$$(7) \quad \lim_{|a| \rightarrow 0^+} \frac{\lambda_0 - \lambda_a}{|a|^k} \text{ is finite and strictly positive as } a \rightarrow 0 \text{ tangentially to a nodal line.}$$

More precisely, the above positive limit can be expressed in terms of the value \mathbf{m}_k defined as follows. Let s_0 be the positive half-axis $s_0 = [0, +\infty) \times \{0\}$. For every odd natural number k , the function

$$(8) \quad \psi_k(r \cos t, r \sin t) = r^{k/2} \sin\left(\frac{k}{2}t\right), \quad r \geq 0, \quad t \in [0, 2\pi],$$

is the unique (up to a multiplicative constant) function which is harmonic on $\mathbb{R}^2 \setminus s_0$, homogeneous of degree $k/2$ and vanishing on s_0 . Let $s := \{(x_1, x_2) \in \mathbb{R}^2 : x_2 = 0 \text{ and } x_1 \geq 1\}$, $\mathbb{R}_+^2 = \{(x_1, x_2) \in \mathbb{R}^2 : x_2 > 0\}$, and denote as $\mathcal{D}_s^{1,2}(\mathbb{R}_+^2)$ the completion of $C_c^\infty(\mathbb{R}_+^2 \setminus s)$ under the norm $(\int_{\mathbb{R}_+^2} |\nabla u|^2 dx)^{1/2}$. By standard minimization methods, the functional

$$J_k : \mathcal{D}_s^{1,2}(\mathbb{R}_+^2) \rightarrow \mathbb{R}, \quad J_k(u) = \frac{1}{2} \int_{\mathbb{R}_+^2} |\nabla u(x)|^2 dx - \int_{\partial \mathbb{R}_+^2 \setminus s} u(x_1, 0) \frac{\partial \psi_k}{\partial x_2}(x_1, 0) dx_1,$$

achieves its minimum over the whole space $\mathcal{D}_s^{1,2}(\mathbb{R}_+^2)$ at some function $w_k \in \mathcal{D}_s^{1,2}(\mathbb{R}_+^2)$, i.e. there exists $w_k \in \mathcal{D}_s^{1,2}(\mathbb{R}_+^2)$ such that

$$(9) \quad \mathbf{m}_k = \min_{u \in \mathcal{D}_s^{1,2}(\mathbb{R}_+^2)} J_k(u) = J_k(w_k).$$

We notice that

$$(10) \quad \mathbf{m}_k = J_k(w_k) = -\frac{1}{2} \int_{\mathbb{R}_+^2} |\nabla w_k(x)|^2 dx = -\frac{1}{2} \int_0^1 \frac{\partial_+ \psi_k}{\partial x_2}(x_1, 0) w_k(x_1, 0) dx_1 < 0,$$

where, for all $x_1 > 0$, $\frac{\partial_+ \psi_k}{\partial x_2}(x_1, 0) = \lim_{t \rightarrow 0^+} \frac{\psi_k(x_1, t) - \psi_k(x_1, 0)}{t} = \frac{k}{2} x_1^{\frac{k}{2}-1}$. In [1] it is proved that the limit in (7) is equal to $-\frac{4}{\pi}(|\beta_1|^2 + |\beta_2|^2) \mathbf{m}_k$ with $(\beta_1, \beta_2) \neq (0, 0)$ being as in (5).

From [1, Theorem 1.2] we can easily deduce that, under assumptions (1) and (4), the Taylor polynomials of the function $a \mapsto \lambda_0 - \lambda_a$ with center 0 and degree strictly smaller than k vanish.

Lemma 1.1. *Let $\Omega \subset \mathbb{R}^2$ be a bounded, open and simply connected domain such that $0 \in \Omega$ and let $n_0 \geq 1$ be such that the n_0 -th eigenvalue $\lambda_0 = \lambda_{n_0}^0$ of $(i\nabla + A_0)^2$ on Ω is simple with associated eigenfunctions having in 0 a zero of order $k/2$ with $k \in \mathbb{N}$ odd. For $a \in \Omega$ let $\lambda_a = \lambda_{n_0}^a$ be the n_0 -th eigenvalue of $(i\nabla + A_a)^2$ on Ω . Then*

$$(11) \quad \lambda_0 - \lambda_a = P(a) + o(|a|^k), \quad \text{as } |a| \rightarrow 0^+,$$

FIGURE 1. $a = |a|(\cos \alpha, \sin \alpha)$ approaches 0 along the direction determined by the angle α .

for some homogeneous polynomial $P \neq 0$ of degree k

$$(12) \quad P(a) = P(a_1, a_2) = \sum_{j=0}^k c_j a_1^{k-j} a_2^j.$$

The aim of the present paper is to detect the exact value of all coefficients of the polynomial P (and hence the sharp asymptotic behavior of $\lambda_a - \lambda_0$ as $a \rightarrow 0$ along any direction, see Figure 1).

Theorem 1.2. *Let $\Omega \subset \mathbb{R}^2$ be a bounded, open and simply connected domain such that $0 \in \Omega$ and let $n_0 \geq 1$ be such that the n_0 -th eigenvalue $\lambda_0 = \lambda_{n_0}^0$ of $(i\nabla + A_0)^2$ on Ω is simple with associated eigenfunctions having in 0 a zero of order $k/2$ with $k \in \mathbb{N}$ odd. For $a \in \Omega$ let $\lambda_a = \lambda_{n_0}^a$ be the n_0 -th eigenvalue of $(i\nabla + A_a)^2$ on Ω . Let $\alpha \in [0, 2\pi)$. Then*

$$\frac{\lambda_0 - \lambda_a}{|a|^k} \rightarrow C_0 \cos(k(\alpha - \alpha_0)) \quad \text{as } a \rightarrow 0 \text{ with } a = |a|(\cos \alpha, \sin \alpha),$$

where α_0 is as in (6) and

$$C_0 = -4 \frac{|\beta_1|^2 + |\beta_2|^2}{\pi} \mathbf{m}_k,$$

with $(\beta_1, \beta_2) \neq (0, 0)$ as in (5) and \mathbf{m}_k as in (9)-(10).

Remark 1.3. By Theorem 1.2 it follows that the polynomial (12) of Lemma 1.1 is given by

$$P(|a|(\cos \alpha, \sin \alpha)) = C_0 |a|^k \cos(k(\alpha - \alpha_0)).$$

Hence

$$P(a_1, a_2) = C_0 \Re e \left(e^{-ik\alpha_0} (a_1 + i a_2)^k \right),$$

thus yielding $\Delta P = 0$, i.e. the polynomial P in (11)-(12) is *harmonic*.

The proof of Theorem 1.2 is based on a combination of estimates from above and below of the Rayleigh quotient associated to the eigenvalue problem with a fine blow-up analysis for scaled eigenfunctions

$$\frac{\varphi_a(|a|x)}{|a|^{k/2}}$$

which gives a sharp characterization of upper and lower bounds for eigenvalues, as already performed in [1]. Nevertheless, differently from [1], in the general case of poles moving along any direction, we cannot explicitly construct the limit profile of the above blow-up sequence. Such a difficulty is overcome studying the dependence of the limit profile on the position of the

pole and the symmetry/periodicity properties of its Fourier coefficient with respect to a basis of eigenvectors of an associated angular problem: such symmetry and periodicity turn into some symmetry and periodicity invariances of the polynomial P . A complete classification of homogeneous k -degree polynomials with such periodicity/symmetry invariances allows us to determine explicitly the polynomial P thus concluding.

The paper is organized as follows. Section 2 is devoted to recall some known facts and introduce some notation. In section 3 we prove sharp asymptotics for $\lambda_0 - \lambda_a$ in dependence of the angle α . In section 4 we describe some symmetry properties of the sharp asymptotics, which allow us to prove Theorem 1.2 in section 5.

2. PRELIMINARIES

In this section we present some preliminaries as needed in the forthcoming argument.

2.1. Change of coordinates. As already highlighted in [1, Remark 2.2], up to a change of coordinates (a rotation), it is not restrictive to assume in (5) that

$$(13) \quad \beta_1 = 0.$$

Under condition (13), we have that $\alpha_0 = 0$ and one nodal line of φ_0 is tangent the x_1 -axis.

2.2. Polar eigenfunctions. The limit function in (5) is an eigenfunction of the operator

$$\mathfrak{L}\psi = -\psi'' + i\psi' + \frac{1}{4}\psi$$

acting on 2π -periodic functions. The eigenvalues of \mathfrak{L} are $\{\frac{j^2}{4} : j \in \mathbb{N}, j \text{ is odd}\}$; moreover each eigenvalue $\frac{j^2}{4}$ has multiplicity 2 and the functions

$$(14) \quad \psi_1^j(t) = \frac{e^{i\frac{t}{2}}}{\sqrt{\pi}} \cos\left(\frac{j}{2}t\right), \quad \psi_2^j(t) = \frac{e^{i\frac{t}{2}}}{\sqrt{\pi}} \sin\left(\frac{j}{2}t\right)$$

form an $L^2((0, 2\pi), \mathbb{C})$ -orthonormal basis of the eigenspace associated to the eigenvalue $\frac{j^2}{4}$.

2.3. Angles and approximating eigenfunctions. As in [2], for every $\alpha \in [0, 2\pi)$ and $b = (b_1, b_2) = |b|(\cos \alpha, \sin \alpha) \in \mathbb{R}^2 \setminus \{0\}$, we define

$$(15) \quad \theta_b : \mathbb{R}^2 \setminus \{b\} \rightarrow [\alpha, \alpha + 2\pi) \quad \text{and} \quad \theta_0^b : \mathbb{R}^2 \setminus \{0\} \rightarrow [\alpha, \alpha + 2\pi)$$

such that

$$\theta_b(b + r(\cos t, \sin t)) = t \quad \text{and} \quad \theta_0^b(r(\cos t, \sin t)) = t, \quad \text{for all } r > 0 \text{ and } t \in [\alpha, \alpha + 2\pi).$$

E.g. if $b_1 > 0$ and $b_2 > 0$ the functions θ_b and θ_0^b are given by

$$(16) \quad \theta_b(x_1, x_2) = \begin{cases} \arctan \frac{x_2 - b_2}{x_1 - b_1}, & \text{if } x_1 > b_1, x_2 \geq \frac{b_2}{b_1}x_1, \\ \frac{\pi}{2}, & \text{if } x_1 = b_1, x_2 > b_2, \\ \pi + \arctan \frac{x_2 - b_2}{x_1 - b_1}, & \text{if } x_1 < b_1, \\ \frac{3}{2}\pi, & \text{if } x_1 = b_1, x_2 < b_2, \\ 2\pi + \arctan \frac{x_2 - b_2}{x_1 - b_1}, & \text{if } x_1 > b_1, x_2 < \frac{b_2}{b_1}x_1, \end{cases}$$

$$\theta_0^b(x_1, x_2) = \begin{cases} \arctan \frac{x_2}{x_1}, & \text{if } x_1 > 0, x_2 \geq \frac{b_2}{b_1}x_1, \\ \frac{\pi}{2}, & \text{if } x_1 = 0, x_2 > 0, \\ \pi + \arctan \frac{x_2}{x_1}, & \text{if } x_1 < 0, \\ \frac{3}{2}\pi, & \text{if } x_1 = 0, x_2 < 0, \\ 2\pi + \arctan \frac{x_2}{x_1}, & \text{if } x_1 > 0, x_2 < \frac{b_2}{b_1}x_1. \end{cases}$$

We notice that θ_b and θ_0^b are regular except on the half-lines

$$s_b := \{tb : t \geq 1\}, \quad s_0^b := \{tb : t \geq 0\},$$

respectively, whereas the difference $\theta_0^b - \theta_b$ is regular except for the segment $\{tb : t \in [0, 1]\}$ from 0 to b .

We also define

$$\theta_0 : \mathbb{R}^2 \setminus \{0\} \rightarrow [0, 2\pi)$$

as

$$(17) \quad \theta_0(x_1, x_2) = \begin{cases} \arctan \frac{x_2}{x_1}, & \text{if } x_1 > 0, x_2 \geq 0, \\ \frac{\pi}{2}, & \text{if } x_1 = 0, x_2 > 0, \\ \pi + \arctan \frac{x_2}{x_1}, & \text{if } x_1 < 0, \\ \frac{3}{2}\pi, & \text{if } x_1 = 0, x_2 < 0, \\ 2\pi + \arctan \frac{x_2}{x_1}, & \text{if } x_1 > 0, x_2 < 0, \end{cases}$$

so that $\theta_0(\cos t, \sin t) = \theta_0^0(\cos t, \sin t) = t$ for all $t \in [0, 2\pi)$ and θ_0 is regular except for the half-axis $\{(x_1, 0) : x_1 \geq 0\}$, whereas the difference

$$(18) \quad (\theta_0^b - \theta_0)(r \cos t, r \sin t) = \begin{cases} 0, & \text{if } t \in [\alpha, 2\pi), \\ 2\pi, & \text{if } t \in [0, \alpha). \end{cases}$$

Let us now consider a suitable family of eigenfunctions relative to the approximating eigenvalue λ_a . For all $a \in \Omega$, let $\varphi_a \in H_0^{1,a}(\Omega, \mathbb{C}) \setminus \{0\}$ be an eigenfunction of problem (E_a) associated to the eigenvalue λ_a , i.e. solving

$$(19) \quad \begin{cases} (i\nabla + A_a)^2 \varphi_a = \lambda_a \varphi_a, & \text{in } \Omega, \\ \varphi_a = 0, & \text{on } \partial\Omega, \end{cases}$$

such that

$$(20) \quad \int_{\Omega} |\varphi_a(x)|^2 dx = 1 \quad \text{and} \quad \int_{\Omega} e^{\frac{i}{2}(\theta_0^a - \theta_a)(x)} \varphi_a(x) \overline{\varphi_0(x)} dx \text{ is a positive real number,}$$

where φ_0 is as in (3). From (1), (3), (19), (20), and standard elliptic estimates, it follows that $\varphi_a \rightarrow \varphi_0$ in $H^1(\Omega, \mathbb{C})$ and in $C_{\text{loc}}^2(\Omega \setminus \{0\}, \mathbb{C})$ and

$$(21) \quad (i\nabla + A_a)\varphi_a \rightarrow (i\nabla + A_0)\varphi_0 \quad \text{in } L^2(\Omega, \mathbb{C}).$$

2.4. Limit profile in dependence on α . A key role in the proof of our main result is played by a suitable magnetic-harmonic function in \mathbb{R}^2 , which will turn out to be the limit of blowed-up sequences of eigenfunctions with poles approaching 0 along the half-line starting from 0 with slope $\tan \alpha$.

For every $\mathbf{p} \in \mathbb{R}^2$, we denote as $\mathcal{D}_{\mathbf{p}}^{1,2}(\mathbb{R}^2, \mathbb{C})$ the completion of $C_c^\infty(\mathbb{R}^N \setminus \{0\}, \mathbb{C})$ with respect to the magnetic Dirichlet norm

$$\|u\|_{\mathcal{D}_{\mathbf{p}}^{1,2}(\mathbb{R}^2, \mathbb{C})} := \left(\int_{\mathbb{R}^2} |(i\nabla + A_{\mathbf{p}})u(x)|^2 dx \right)^{1/2}.$$

We recall from [5] that functions in $\mathcal{D}_{\mathbf{p}}^{1,2}(\mathbb{R}^2, \mathbb{C})$ satisfy the Hardy type inequality

$$\int_{\mathbb{R}^2} |(i\nabla + A_{\mathbf{p}})u|^2 dx \geq \frac{1}{4} \int_{\mathbb{R}^2} \frac{|u(x)|^2}{|x - \mathbf{p}|^2} dx;$$

furthermore (see also [3, Lemma 3.1 and Remark 3.2]) the inequality

$$\int_{D_r(\mathbf{p})} |(i\nabla + A_{\mathbf{p}})u|^2 dx \geq \frac{1}{4} \int_{D_r(\mathbf{p})} \frac{|u(x)|^2}{|x - \mathbf{p}|^2} dx,$$

holds for all $r > 0$ and $u \in H^{1,\mathbf{p}}(D_r(\mathbf{p}), \mathbb{C})$, where $D_r(\mathbf{p})$ denotes the disk of center \mathbf{p} and radius r .

Proposition 2.1. *Let $\alpha \in [0, 2\pi)$ and $\mathbf{p} = (\cos \alpha, \sin \alpha)$. There exists a unique function $\Psi_{\mathbf{p}} \in H_{\text{loc}}^{1,\mathbf{p}}(\mathbb{R}^2, \mathbb{C})$ such that*

$$(22) \quad (i\nabla + A_{\mathbf{p}})^2 \Psi_{\mathbf{p}} = 0 \quad \text{in } \mathbb{R}^2 \text{ in a weak } H^{1,\mathbf{p}}\text{-sense,}$$

and

$$(23) \quad \int_{\mathbb{R}^2 \setminus D_r} |(i\nabla + A_{\mathbf{p}})(\Psi_{\mathbf{p}} - e^{\frac{i}{2}(\theta_{\mathbf{p}} - \theta_0^{\mathbf{p}})} e^{\frac{i}{2}\theta_0} \psi_k)|^2 dx < +\infty, \quad \text{for any } r > 1,$$

where $D_r = D_r(0)$.

Proof. Let η be a smooth cut-off function such that $\eta \equiv 0$ in D_1 and $\eta \equiv 1$ in $\mathbb{R}^2 \setminus D_R$ for some $R > 1$. We observe that

$$\begin{aligned} F &= (\Delta \eta) e^{\frac{i}{2}(\theta_{\mathbf{p}} - \theta_0^{\mathbf{p}})} e^{\frac{i}{2}\theta_0} \psi_k - 2i\nabla \eta \cdot (i\nabla + A_{\mathbf{p}}) \left(e^{\frac{i}{2}(\theta_{\mathbf{p}} - \theta_0^{\mathbf{p}})} e^{\frac{i}{2}\theta_0} \psi_k \right) \\ &= -(i\nabla + A_{\mathbf{p}})^2 \left(\eta e^{\frac{i}{2}(\theta_{\mathbf{p}} - \theta_0^{\mathbf{p}})} e^{\frac{i}{2}\theta_0} \psi_k \right) \in (\mathcal{D}_{\mathbf{p}}^{1,2}(\mathbb{R}^2, \mathbb{C}))^*. \end{aligned}$$

Hence, via Lax-Milgram's Theorem there exists a unique solution $g \in \mathcal{D}_{\mathbf{p}}^{1,2}(\mathbb{R}^2, \mathbb{C})$ to problem

$$(i\nabla + A_{\mathbf{p}})^2 g = F, \quad \text{in } (\mathcal{D}_{\mathbf{p}}^{1,2}(\mathbb{R}^2, \mathbb{C}))^*.$$

The function $\Psi_{\mathbf{p}} = g + \eta e^{\frac{i}{2}(\theta_{\mathbf{p}} - \theta_0^{\mathbf{p}})} e^{\frac{i}{2}\theta_0} \psi_k$ satisfies (22) and (23).

To prove uniqueness, it is enough to observe that, if two function $\Psi_{\mathbf{p}}^1, \Psi_{\mathbf{p}}^2 \in H_{\text{loc}}^{1,\mathbf{p}}(\mathbb{R}^2, \mathbb{C})$ satisfy (22) and (23), then their difference $\Psi_{\mathbf{p}}^1 - \Psi_{\mathbf{p}}^2$ belongs to the space $\mathcal{D}_{\mathbf{p}}^{1,2}(\mathbb{R}^2, \mathbb{C})$ (see [1, Proposition 4.3]); since $(i\nabla + A_{\mathbf{p}})^2(\Psi_{\mathbf{p}}^1 - \Psi_{\mathbf{p}}^2) = 0$ in $(\mathcal{D}_{\mathbf{p}}^{1,2}(\mathbb{R}^2, \mathbb{C}))^*$, we conclude that necessarily $\Psi_{\mathbf{p}}^1 - \Psi_{\mathbf{p}}^2 \equiv 0$. \square

Remark 2.2. We observe that from [3, Theorem 1.5] it follows easily that

$$\Psi_{\mathbf{p}} - e^{\frac{i}{2}(\theta_{\mathbf{p}} - \theta_0^{\mathbf{p}})} e^{\frac{i}{2}\theta_0} \psi_k = O(|x|^{-1/2}), \quad \text{as } |x| \rightarrow +\infty.$$

3. SHARP ASYMPTOTICS FOR $\lambda_0 - \lambda_a$ IN DEPENDENCE ON α

As in [1], the argument relies essentially on the Courant-Fisher minimax characterization of eigenvalues. The asymptotics for eigenvalues is derived by combining estimates from above and below of the Rayleigh quotient, obtained by using as test functions suitable manipulations of eigenfunctions. In this way, we prove upper and lower bounds whose limit as $a \rightarrow 0$ can be described in terms of the limit profile constructed in Proposition 2.1.

For all $1 \leq j \leq n_0$ and $a \in \Omega$, let $\varphi_j^a \in H_0^{1,a}(\Omega, \mathbb{C}) \setminus \{0\}$ be an eigenfunction of problem (E_a) associated to the eigenvalue λ_j^a , i.e. solving

$$(24) \quad \begin{cases} (i\nabla + A_a)^2 \varphi_j^a = \lambda_j^a \varphi_j^a, & \text{in } \Omega, \\ \varphi_j^a = 0, & \text{on } \partial\Omega, \end{cases}$$

such that

$$(25) \quad \int_{\Omega} |\varphi_j^a(x)|^2 dx = 1 \quad \text{and} \quad \int_{\Omega} \varphi_j^a(x) \overline{\varphi_{\ell}^a(x)} dx = 0 \quad \text{if } j \neq \ell.$$

For $j = n_0$, we choose

$$(26) \quad \varphi_{n_0}^a = \varphi_a,$$

with φ_a as in (19)–(20).

3.1. Rayleigh quotient for λ_a . We revisit [1, Subsection 6.2], whose main strategy does not differ in this case; however, it is worth presenting here the key points, in order to highlight the dependence of the result on the position of the blown-up pole.

By the Courant-Fisher *minimax characterization* of the eigenvalue λ_a , we have that

$$(27) \quad \lambda_a = \min \left\{ \max_{u \in F \setminus \{0\}} \frac{\int_{\Omega} |(i\nabla + A_a)u|^2 dx}{\int_{\Omega} |u|^2 dx} : F \text{ is a subspace of } H_0^{1,a}(\Omega, \mathbb{C}), \dim F = n_0 \right\}.$$

Let $R > 2$ and $\alpha \in [0, 2\pi)$. For $a = |a|(\cos \alpha, \sin \alpha)$ with $|a|$ sufficiently small, we consider the functions $w_{j,R,a}$ defined as

$$w_{j,R,a} = \begin{cases} w_{j,R,a}^{ext}, & \text{in } \Omega \setminus D_{R|a|}, \\ w_{j,R,a}^{int}, & \text{in } D_{R|a|}, \end{cases} \quad j = 1, \dots, n_0,$$

where

$$w_{j,R,a}^{ext} := e^{\frac{i}{2}(\theta_a - \theta_0^a)} \varphi_j^0 \quad \text{in } \Omega \setminus D_{R|a|},$$

with φ_j^0 as in (24)–(26) with $a = 0$, so that it solves

$$\begin{cases} (i\nabla + A_a)^2 w_{j,R,a}^{ext} = \lambda_j^0 w_{j,R,a}^{ext}, & \text{in } \Omega \setminus D_{R|a|}, \\ w_{j,R,a}^{ext} = e^{\frac{i}{2}(\theta_a - \theta_0^a)} \varphi_j^0, & \text{on } \partial(\Omega \setminus D_{R|a|}), \end{cases}$$

whereas $w_{j,R,a}^{int}$ is the unique solution to the minimization problem

$$\begin{aligned} & \int_{D_{R|a|}} |(i\nabla + A_a)w_{j,R,a}^{int}(x)|^2 dx \\ &= \min \left\{ \int_{D_{R|a|}} |(i\nabla + A_a)u(x)|^2 dx : u \in H^{1,a}(D_{R|a|}, \mathbb{C}), u = e^{\frac{i}{2}(\theta_a - \theta_0^a)} \varphi_j^0 \text{ on } \partial D_{R|a|} \right\}, \end{aligned}$$

thus solving

$$\begin{cases} (i\nabla + A_a)^2 w_{j,R,a}^{int} = 0, & \text{in } D_{R|a|}, \\ w_{j,R,a}^{int} = e^{\frac{i}{2}(\theta_a - \theta_0^a)} \varphi_j^0, & \text{on } \partial D_{R|a|}. \end{cases}$$

Following the argument in [1, Subsection 6.2], letting $\mathbf{p} = (\cos \alpha, \sin \alpha)$, we now define the function w_R as the unique solution to the minimization problem

$$\begin{aligned} & \int_{D_R} |(i\nabla + A_{\mathbf{p}})w_R(x)|^2 dx \\ &= \min \left\{ \int_{D_R} |(i\nabla + A_{\mathbf{p}})u(x)|^2 dx : u \in H^{1,\mathbf{p}}(D_R, \mathbb{C}), u = e^{\frac{i}{2}(\theta_{\mathbf{p}} - \theta_0^{\mathbf{p}})} e^{\frac{i}{2}\theta_0} \psi_k \text{ on } \partial D_R \right\}, \end{aligned}$$

which then solves

$$(28) \quad \begin{cases} (i\nabla + A_{\mathbf{p}})^2 w_R = 0, & \text{in } D_R, \\ w_R = e^{\frac{i}{2}(\theta_{\mathbf{p}} - \theta_0^{\mathbf{p}})} e^{\frac{i}{2}\theta_0} \psi_k, & \text{on } \partial D_R. \end{cases}$$

We also introduce the following blow-up sequences as in [1]:

$$(29) \quad U_a^R(x) := \frac{w_{n_0,R,a}^{int}(|a|x)}{|a|^{k/2}}, \quad W_a(x) := \frac{\varphi_0(|a|x)}{|a|^{k/2}}.$$

As in [1], under assumptions (4) and (13), from [3, Theorem 1.3 and Lemma 6.1] we have that

$$(30) \quad W_a \rightarrow \beta e^{\frac{i}{2}\theta_0} \psi_k \quad \text{as } |a| \rightarrow 0$$

in $H^{1,0}(D_R, \mathbb{C})$ for every $R > 1$, where ψ_k is defined in (8) and

$$(31) \quad \beta := \frac{\beta_2}{\sqrt{\pi}}$$

with β_2 as in (5). On the other hand, we now meet the following differences with respect to the case $\alpha = 0$ studied in [1]:

- By the Dirichlet principle and (30), we have that

$$\begin{aligned} & \int_{D_R} |(i\nabla + A_{\mathbf{p}})(U_a^R - \beta w_R)|^2 dx \\ & \leq \int_{D_R} \left| (i\nabla + A_{\mathbf{p}})(\eta_R e^{\frac{i}{2}(\theta_{\mathbf{p}} - \theta_0^{\mathbf{p}})} (W_a - \beta e^{\frac{i}{2}\theta_0} \psi_k)) \right|^2 dx \\ & \leq 2 \int_{D_R} |\nabla \eta_R|^2 |W_a - \beta e^{\frac{i}{2}\theta_0} \psi_k|^2 dx \\ & \quad + 2 \int_{D_R \setminus D_{R/2}} \eta_R^2 |(i\nabla + A_0)(W_a - \beta e^{\frac{i}{2}\theta_0} \psi_k)|^2 dx = o(1) \quad \text{as } |a| \rightarrow 0^+, \end{aligned}$$

where $\eta_R : \mathbb{R}^2 \rightarrow \mathbb{R}$ is a smooth cut-off function such that

$$\eta_R \equiv 0 \text{ in } D_{R/2}, \quad \eta_R \equiv 1 \text{ on } \mathbb{R}^2 \setminus D_R, \quad |\nabla \eta_R| \leq 4/R \text{ in } \mathbb{R}^2.$$

Hence, for all $R > 2$, $U_a^R \rightarrow \beta w_R$ in $H^{1,\mathbf{p}}(D_R, \mathbb{C})$ as $a = |a|\mathbf{p} \rightarrow 0$, where β is defined in (31).

- For every $r > 1$, $w_R \rightarrow \Psi_{\mathbf{p}}$ in $H^{1,\mathbf{p}}(D_r, \mathbb{C})$ as $R \rightarrow +\infty$. This follows as in the proof of [1, Lemma 6.5] up to suitable obvious modifications and taking into account (23) and Remark 2.2.

Taking into account what observed above and using (after a Gram-Schmidt normalization) the functions $w_{j,R,a}$ as test functions in the Rayleigh quotient, we can argue as in [1, Lemma 6.6] to obtain the following estimate.

Lemma 3.1. *For $\alpha \in [0, 2\pi)$ and $a = |a|(\cos \alpha, \sin \alpha) \in \Omega$, let $\lambda_a \in \mathbb{R}$ and $\varphi_a \in H_0^{1,a}(\Omega, \mathbb{C})$ solve (19-20) and $\lambda_0 \in \mathbb{R}$ and $\varphi_0 \in H_0^{1,0}(\Omega, \mathbb{C})$ solve (3). If (1) and (4) hold and (13) is satisfied, then, for all $R > \tilde{R}$ and $a = |a|(\cos \alpha, \sin \alpha) \in \Omega$,*

$$\frac{\lambda_0 - \lambda_a}{|a|^k} \geq g_R(a)$$

where

$$\lim_{|a| \rightarrow 0} g_R(a) = i|\beta|^2 \tilde{\kappa}_R,$$

with β as in (31) and

$$(32) \quad \tilde{\kappa}_R = \int_{\partial D_R} \left(e^{-\frac{i}{2}\theta_{\mathbf{p}}} e^{\frac{i}{2}(\theta_0^{\mathbf{p}} - \theta_0)} (i\nabla + A_{\mathbf{p}}) w_R \cdot \nu - (i\nabla) \psi_k \cdot \nu \right) \psi_k ds$$

being $\mathbf{p} = (\cos \alpha, \sin \alpha)$ and ψ_k as in (8).

Proof. The proof follows exactly as in [1, Lemma 6.6], so we omit it. \square

For any $R > 1$ let us introduce the following Fourier-type coefficient

$$(33) \quad v_R(r) := \int_0^{2\pi} e^{-\frac{i}{2}\theta_{\mathbf{p}}(r \cos t, r \sin t)} w_R(r \cos t, r \sin t) e^{\frac{i}{2}\theta_0^{\mathbf{p}}(r \cos t, r \sin t)} \overline{\psi_2^k(t)}, \quad r \in [1, R],$$

with ψ_2^k defined in (14).

Lemma 3.2. *For any $R > 1$ the function v_R defined in (33) satisfies*

$$(34) \quad (r^{-k/2} v_R(r))' = \frac{c_R}{r^{1+k}}, \quad \text{in } (1, R),$$

for some $c_R \in \mathbb{C}$.

Proof. To prove (34) it is enough to show that

$$\int_1^R \left(-v_R'' - \frac{1}{r} v_R' + \frac{k^2}{4r^2} v_R \right) r \eta(r) dr = 0, \quad \text{for all } \eta \in C_c^\infty(1, R).$$

By (28), it is easy to see that the function $u(x) := e^{-\frac{i}{2}\theta_{\mathbf{p}}(x)} w_R(x)$ is harmonic in $D_R \setminus s_{\mathbf{p}}$. Let us consider an arbitrary function $\eta(r) \in C_c^\infty(1, R)$ and the function

$$g(t) := \frac{1}{\sqrt{\pi}} e^{\frac{i}{2}(\theta_0^{\mathbf{p}} - \theta_0)(\cos t, \sin t)} \sin\left(\frac{k}{2}t\right) = \begin{cases} -\frac{1}{\sqrt{\pi}} \sin\left(\frac{k}{2}t\right) & t \in [0, \alpha) \\ \frac{1}{\sqrt{\pi}} \sin\left(\frac{k}{2}t\right) & t \in [\alpha, 2\pi). \end{cases}$$

Testing equation $-\Delta u = 0$ with $v(r \cos t, r \sin t) = \eta(r)g(t)$ in $D_R \setminus s_{\mathbf{p}}$, integrating by parts and observing that both v and ∇u jump across $s_{\mathbf{p}}$, we obtain that

$$\begin{aligned} 0 &= \int_1^R \left(\int_0^{2\pi} \left(r \partial_r u(r \cos t, r \sin t) \eta'(r) g(t) + \frac{\eta(r)}{r} g'(t) \partial_t u(r \cos t, r \sin t) \right) dt \right) dr \\ &= - \int_1^R \eta(r) \left(\int_0^{2\pi} \left(\partial_r u(r \cos t, r \sin t) + r \partial_{rr}^2 u(r \cos t, r \sin t) \right) g(t) dt \right) dr \\ &\quad + \int_1^R \frac{\eta(r)}{r} \left(\int_0^{2\pi} \partial_t u(r \cos t, r \sin t) g'(t) dt \right) dr \\ &= - \int_1^R \left(\eta(r) v'_R(r) + r \eta(r) v''_R(r) \right) dr + \int_1^R \frac{\eta(r)}{r} \left(\int_0^{2\pi} \partial_t u(r \cos t, r \sin t) g'(t) dt \right) dr. \end{aligned}$$

A further integration by parts yields

$$\begin{aligned} \int_0^{2\pi} \partial_t u(r \cos t, r \sin t) g'(t) dt &= - \int_0^{2\pi} u(r \cos t, r \sin t) g''(t) dt \\ &\quad + g'_-(2\pi) u(r \cos(2\pi^-), r \sin(2\pi^-)) - g'_+(\alpha) u(r \cos(\alpha^+), r \sin(\alpha^+)) \\ &\quad + g'_-(\alpha) u(r \cos(\alpha^-), r \sin(\alpha^-)) - g'_+(0) u(r \cos(0^+), r \sin(0^+)) \\ &= - \int_0^{2\pi} u(r \cos t, r \sin t) g''(t) dt = \frac{k^2}{4} \int_0^{2\pi} u(r \cos t, r \sin t) g(t) dt = \frac{k^2}{4} v_R(r) \end{aligned}$$

in view of the fact that $g'_+(0) = g'_-(2\pi)$, $g'_+(\alpha) = -g'_-(\alpha)$, and

$$\lim_{t \rightarrow \alpha^+} u(r \cos(t), r \sin(t)) = - \lim_{t \rightarrow \alpha^-} u(r \cos(t), r \sin(t)).$$

The conclusion then follows. \square

For $\alpha \in [0, 2\pi)$ and $\mathbf{p} = (\cos \alpha, \sin \alpha)$, let us define the following Fourier-type coefficient of the limit profile $\Psi_{\mathbf{p}}$

$$(35) \quad \xi_{\mathbf{p}}(r) := \int_0^{2\pi} e^{-\frac{i}{2}\theta_{\mathbf{p}}(r \cos t, r \sin t)} \Psi_{\mathbf{p}}(r \cos t, r \sin t) e^{\frac{i}{2}\theta_{\mathbf{p}}^{\mathbf{p}}(r \cos t, r \sin t)} \overline{\psi_{\frac{k}{2}}^k(t)} dt, \quad r \geq 1.$$

Lemma 3.3. *Let $\tilde{\kappa}_R$ be as in (32). Then*

$$\lim_{R \rightarrow +\infty} \tilde{\kappa}_R = ik\sqrt{\pi}(\sqrt{\pi} - \xi_{\mathbf{p}}(1)),$$

where $\xi_{\mathbf{p}}(r)$ is defined in (35).

Proof. Arguing as in the proof of [1, Lemma 6.7], integrating (34) and taking into account the boundary condition in (28), we obtain that

$$v_R(r) = r^{k/2} \frac{R^k \sqrt{\pi} - v_R(1)}{R^k - 1} - r^{-k/2} \frac{R^k (\sqrt{\pi} - v_R(1))}{R^k - 1}, \quad \text{for all } r \in (1, R].$$

By differentiation of the previous identity, we obtain that

$$(36) \quad v'_R(R) = \frac{k}{2} \frac{R^{\frac{k}{2}-1}}{R^k - 1} \left((R^k + 1) \sqrt{\pi} - 2v_R(1) \right).$$

On the other hand, differentiation in (33) yields

$$(37) \quad v'_R(r) = -\frac{i}{\sqrt{\pi}} r^{-1-\frac{k}{2}} \int_{\partial D_r} e^{-\frac{i}{2}(\theta_{\mathbf{p}} - \theta_{\mathbf{p}}^{\mathbf{p}})} (i\nabla + A_{\mathbf{p}}) w_R \cdot \nu e^{-\frac{i}{2}\theta_0} \psi_k ds.$$

Combination of (36), (37) and (32) yields that

$$\tilde{\kappa}_R = \frac{ik\sqrt{\pi}R^k}{R^k - 1}(\sqrt{\pi} - v_R(1)).$$

We conclude by letting $R \rightarrow +\infty$, since the convergence $w_R \rightarrow \Psi_{\mathbf{p}}$ in $H^{1,\mathbf{p}}(D_r, \mathbb{C})$ as $R \rightarrow +\infty$ implies that $\lim_{R \rightarrow +\infty} v_R(1) = \xi_{\mathbf{p}}(1)$. \square

Combining the results of Lemmas 3.1 and 3.3 we have that

$$(38) \quad \lambda_0 - \lambda_a \geq |a|^k k |\beta|^2 \sqrt{\pi} \left(\xi_{\mathbf{p}}(1) - \sqrt{\pi} + o(1) \right)$$

as $a = |a|\mathbf{p} \rightarrow 0$.

3.2. Blow-up analysis and Rayleigh quotient for λ_0 . In order to prove even an upper bound for the difference $\lambda_0 - \lambda_a$ we refer this time to [1, Subsection 6.1]. Differently from what occurs in [1], when the direction along which $a \rightarrow 0$ is not a nodal line of φ_0 the value $(\xi_{\mathbf{p}}(1) - \sqrt{\pi})$ can have any sign (and vanish along some directions); this does not allow deriving the exact asymptotic behavior of the normalization term in the blow-up analysis from estimates of the Rayleigh quotient from above and below as done in [1]. On the other hand, from [1] we can derive Lemma 1.1 and hence a control on the size of the eigenvalue variation along any direction.

The proof of Lemma 1.1 is based on the following result (see also [2, Lemma 6.6]).

Lemma 3.4. *Let $Q(x_1, x_2) = \sum_{j=0}^h c_j x_1^j x_2^{h-j}$ be a homogeneous polynomial in two variables x_1, x_2 of degree at most $h \in \mathbb{N}$. If there exist $\bar{\theta} \in [0, 2\pi)$ and an odd natural number k such that $k > h$ and*

$$(39) \quad Q\left(\cos\left(\bar{\theta} + j\frac{2\pi}{k}\right), \sin\left(\bar{\theta} + j\frac{2\pi}{k}\right)\right) = 0, \quad \text{for all } j = 0, 1, \dots, k-1,$$

then $Q \equiv 0$.

Proof. Up to a rotation, it is not restrictive to assume that $\bar{\theta} = 0$. If $x_1 \neq 0$, we can write Q as

$$Q(x_1, x_2) = x_1^h \tilde{Q}\left(\frac{x_2}{x_1}\right), \quad \text{where } \tilde{Q}(t) = \sum_{j=0}^h c_j t^{h-j}.$$

Since k is odd, we have that $\cos\left(j\frac{2\pi}{k}\right) \neq 0$ for all $j = 0, 1, \dots, k-1$. Then, from assumption (39) it follows that $\tilde{Q}\left(\tan\left(j\frac{2\pi}{k}\right)\right) = 0$ for all $j = 0, 1, \dots, k-1$. Since k is odd, we also have that $\tan\left(j\frac{2\pi}{k}\right) \neq \tan\left(\ell\frac{2\pi}{k}\right)$ for all $j, \ell \in \{0, 1, \dots, k-1\}$ with $j \neq \ell$. Hence \tilde{Q} has k distinct zeros. Since \tilde{Q} is a polynomial of degree at most h and $h < k$, from the Fundamental Theorem of Algebra we conclude $\tilde{Q} \equiv 0$, i.e. $c_j = 0$ for all $j = 0, 1, \dots, k-1$. Hence $Q \equiv 0$. \square

Proof of Lemma 1.1. Since the function $a = (a_1, a_2) \mapsto \lambda_0 - \lambda_a$ is C^∞ in a neighborhood of 0 (see [2, Theorem 1.3]), it admits a Taylor expansion up to order k of the form

$$\lambda_0 - \lambda_a = \sum_{j=1}^k P_j(a_1, a_2) + o(|a|^k), \quad \text{as } |a| \rightarrow 0,$$

where, for every $j = 1, \dots, k$, $P_j(a_1, a_2)$ is either identically zero or a homogeneous polynomial in the two variables a_1, a_2 of degree j . From [1, Theorem 1.2] (see also (7)) we have that, for every $\ell < k$,

$$P_\ell\left(\cos\left(\alpha_0 + j\frac{2\pi}{k}\right), \sin\left(\alpha_0 + j\frac{2\pi}{k}\right)\right) = 0, \quad \text{for all } j = 0, 1, \dots, k-1,$$

where α_0 is as in (6) (i.e. $\alpha_0 + j\frac{2\pi}{k}$, with $j = 0, 1, \dots, k-1$, identify the directions of the k half-lines tangent to the nodal lines of the eigenfunctions associated to λ_0). The conclusion follows directly from Lemma 3.4. \square

From the expansion (11)- (12) in Lemma 1.1 it follows that

$$(40) \quad |\lambda_a - \lambda_0| = O(|a|^k)$$

as $|a| \rightarrow 0$ along any direction. Exploiting (40) we can perform a sharp blow-up analysis prior to the estimate from above of the eigenvalue variation $\lambda_0 - \lambda_a$.

Let $\alpha \in [0, 2\pi)$ and $\mathbf{p} = (\cos \alpha, \sin \alpha)$. Arguing as in [1] we can prove that, for every $\delta \in (0, 1/4)$, there exist $r_\delta, K_\delta > 0$ such that, for all $R \geq K_\delta$,

$$(41) \quad \text{the family of functions } \{\tilde{\varphi}_a : a = |a|\mathbf{p}, |a| < \frac{r_\delta}{R}\} \text{ is bounded in } H^{1,\mathbf{p}}(D_R, \mathbb{C})$$

where

$$(42) \quad \tilde{\varphi}_a(x) := \frac{\varphi_a(|a|x)}{\sqrt{H_{a,\delta}}},$$

and

$$H_{a,\delta} := \frac{1}{K_\delta|a|} \int_{\partial D_{K_\delta|a|}} |\varphi_a|^2 ds.$$

Furthermore, from [1, Estimates (113) and (114)] we have that

$$(43) \quad H_{a,\delta} \geq C_\delta |a|^{k+2\delta}, \quad \text{if } |a| < \frac{r_\delta}{K_\delta},$$

for some $C_\delta > 0$ independent of a , and

$$(44) \quad H_{a,\delta} = O(|a|^{1-2\delta}) \quad \text{as } |a| \rightarrow 0.$$

For a precise proof of such estimates we refer the reader to [1]. Here we only mention that they proceed from suitable integrations of the monotonicity formula.

We observe that $\tilde{\varphi}_a$ weakly solves

$$(45) \quad (i\nabla + A_{\mathbf{p}})^2 \tilde{\varphi}_a = |a|^2 \lambda_a \tilde{\varphi}_a, \quad \text{in } \frac{1}{|a|}\Omega = \{x \in \mathbb{R}^2 : |a|x \in \Omega\},$$

and

$$(46) \quad \frac{1}{K_\delta} \int_{\partial D_{K_\delta}} |\tilde{\varphi}_a|^2 ds = 1.$$

Let $R > 2$. For $|a|$ sufficiently small we define the functions $v_{j,R,a}$ as follows:

$$v_{j,R,a} = \begin{cases} v_{j,R,a}^{ext}, & \text{in } \Omega \setminus D_{R|a|}, \\ v_{j,R,a}^{int}, & \text{in } D_{R|a|}, \end{cases} \quad j = 1, \dots, n_0,$$

where

$$v_{j,R,a}^{ext} := e^{\frac{i}{2}(\theta_0^a - \theta_a)} \varphi_j^a \quad \text{in } \Omega \setminus D_{R|a|},$$

with φ_j^a as in (24)–(26) and θ_a, θ_0^a as in (15) (notice that $e^{\frac{i}{2}(\theta_0^a - \theta_a)}$ is smooth in $\Omega \setminus D_{R|a|}$), so that it solves

$$\begin{cases} (i\nabla + A_0)^2 v_{j,R,a}^{ext} = \lambda_j^a v_{j,R,a}^{ext} & \text{in } \Omega \setminus D_{R|a|}, \\ v_{j,R,a}^{ext} = e^{\frac{i}{2}(\theta_0^a - \theta_a)} \varphi_j^a & \text{on } \partial(\Omega \setminus D_{R|a|}), \end{cases}$$

whereas $v_{j,R,a}^{int}$ is the unique solution to the minimization problem

$$\begin{aligned} & \int_{D_{R|a|}} |(i\nabla + A_0)v_{j,R,a}^{int}(x)|^2 dx \\ & = \min \left\{ \int_{D_{R|a|}} |(i\nabla + A_0)u(x)|^2 dx : u \in H^{1,0}(D_{R|a|}, \mathbb{C}), u = e^{\frac{i}{2}(\theta_0^a - \theta_a)} \varphi_j^a \text{ on } \partial D_{R|a|} \right\}, \end{aligned}$$

so that it solves

$$\begin{cases} (i\nabla + A_0)^2 v_{j,R,a}^{int} = 0, & \text{in } D_{R|a|}, \\ v_{j,R,a}^{int} = e^{\frac{i}{2}(\theta_0^a - \theta_a)} \varphi_j^a, & \text{on } \partial D_{R|a|}. \end{cases}$$

It is easy to verify that $\dim(\text{span}\{v_{1,R,a}, \dots, v_{n_0,R,a}\}) = n_0$.

For all $R > 2$ and $a = |a|\mathbf{p} \in \Omega$ with $|a|$ small, we define

$$(47) \quad Z_a^R(x) := \frac{v_{n_0,R,a}^{int}(|a|x)}{\sqrt{H_{a,\delta}}}.$$

Arguing as in [1, Lemma 6.2] we can prove that, as a consequence of (41) and the Dirichlet principle,

$$(48) \quad \text{the family of functions } \{Z_a^R : a = |a|\mathbf{p}, |a| < \frac{r_\delta}{R}\} \text{ is bounded in } H^{1,0}(D_R, \mathbb{C}).$$

Theorem 3.5. *For every $R > 2$,*

$$\|v_{n_0,R,a} - \varphi_0\|_{H_0^{1,0}(\Omega, \mathbb{C})} = O\left(\sqrt{H_{a,\delta}}\right) \quad \text{as } a = |a|\mathbf{p} \rightarrow 0.$$

Proof. Let $R > 2$. We first notice that $v_{n_0,R,a} \rightarrow \varphi_0$ in $H_0^{1,0}(\Omega, \mathbb{C})$ as $|a| \rightarrow 0^+$. Indeed

$$\begin{aligned} & \int_{\Omega} |(i\nabla + A_0)(v_{n_0,R,a} - \varphi_0)|^2 dx = \int_{\Omega} |e^{\frac{i}{2}(\theta_0^a - \theta_a)}(i\nabla + A_a)\varphi_a - (i\nabla + A_0)\varphi_0|^2 dx \\ & \quad + \int_{D_R} \left| \sqrt{H_{a,\delta}}(i\nabla + A_0)Z_a^R - |a|^{k/2}(i\nabla + A_0)W_a \right|^2 dx \\ & \quad - \int_{D_R} \left| \sqrt{H_{a,\delta}}e^{\frac{i}{2}(\theta_0^a - \theta_a)}(i\nabla + A_{\mathbf{p}})\tilde{\varphi}_a - |a|^{k/2}(i\nabla + A_0)W_a \right|^2 dx = o(1) \end{aligned}$$

in view of (21), (41), (48), (30) and (44).

From [1, Lemma 7.1] the function

$$\begin{aligned} F : \mathbb{C} \times H_0^{1,0}(\Omega, \mathbb{C}) & \longrightarrow \mathbb{R} \times \mathbb{R} \times (H_{0,\mathbb{R}}^{1,0}(\Omega, \mathbb{C}))^* \\ (\lambda, \varphi) & \longmapsto \left(\|\varphi\|_{H_0^{1,0}(\Omega, \mathbb{C})}^2 - \lambda_0, \Im \left(\int_{\Omega} \varphi \overline{\varphi_0} dx \right), (i\nabla + A_0)^2 \varphi - \lambda \varphi \right) \end{aligned}$$

is Fréchet-differentiable at (λ_0, φ_0) and its Fréchet-differential $dF(\lambda_0, \varphi_0)$ is invertible. In the above definition, $(H_{0,\mathbb{R}}^{1,0}(\Omega, \mathbb{C}))^*$ is the real dual space of $H_{0,\mathbb{R}}^{1,0}(\Omega, \mathbb{C}) = H_0^{1,0}(\Omega, \mathbb{C})$, which is

here meant as a vector space over \mathbb{R} endowed with the norm

$$\|u\|_{H_0^{1,0}(\Omega, \mathbb{C})} = \left(\int_{\Omega} |(i\nabla + A_0)u|^2 dx \right)^{1/2}.$$

Therefore

$$\begin{aligned} & |\lambda_a - \lambda_0| + \|v_{n_0, R, a} - \varphi_0\|_{H_0^{1,0}(\Omega, \mathbb{C})} \\ & \leq \|(dF(\lambda_0, \varphi_0))^{-1}\|_{\mathcal{L}(\mathbb{R} \times \mathbb{R} \times (H_0^{1,0}(\Omega, \mathbb{C}))^*, \mathbb{C} \times H_0^{1,0}(\Omega, \mathbb{C}))} \|F(\lambda_a, v_{n_0, R, a})\|_{\mathbb{R} \times \mathbb{R} \times (H_0^{1,0}(\Omega, \mathbb{C}))^*} (1 + o(1)) \end{aligned}$$

as $|a| \rightarrow 0^+$. To prove the theorem it is then enough to estimate the norm of

$$\begin{aligned} F(\lambda_a, v_{n_0, R, a}) &= (\alpha_a, \beta_a, w_a) \\ &= \left(\|v_{n_0, R, a}\|_{H_0^{1,0}(\Omega, \mathbb{C})}^2 - \lambda_0, \Im \left(\int_{\Omega} v_{n_0, R, a} \overline{\varphi_0} dx \right), (i\nabla + A_0)^2 v_{n_0, R, a} - \lambda_a v_{n_0, R, a} \right) \end{aligned}$$

in $\mathbb{R} \times \mathbb{R} \times (H_0^{1,0}(\Omega, \mathbb{C}))^*$. The estimates of β_a and w_a can be performed as in [1, Proof of Theorem 7.2] obtaining that

$$\beta_a = o(\sqrt{H_{a, \delta}}) \quad \text{and} \quad \|w_a\|_{(H_0^{1,0}(\Omega, \mathbb{C}))^*} = O(\sqrt{H_{a, \delta}}),$$

as $a = |a|\mathbf{p} \rightarrow 0$. As far as α_a is concerned, differently from [1], the estimate of [1, Proposition 6.10] which, in the case $\alpha = 0$, implied that $|\lambda_a - \lambda_0| = O(H_{a, \delta})$, is not available after preliminary estimates of the Rayleigh quotient for generic values of α since $(\xi_{\mathbf{p}}(1) - \sqrt{\pi})$ can have any sign. This difficulty can be overcome by observing that (43) and (40) imply that $|\lambda_a - \lambda_0| = O(|a|^{\frac{k}{2} - \delta} \sqrt{H_{a, \delta}})$ and then

$$|\lambda_a - \lambda_0| = o(\sqrt{H_{a, \delta}}),$$

as $a = |a|\mathbf{p} \rightarrow 0$. Then, from (41) and (48), we obtain that

$$\begin{aligned} \alpha_a &= \left(\int_{D_{R|a|}} |(i\nabla + A_0)v_{n_0, R, a}^{int}|^2 dx - \int_{D_{R|a|}} |(i\nabla + A_a)\varphi_a|^2 dx \right) + (\lambda_a - \lambda_0) \\ &= H_{a, \delta} \left(\int_{D_R} |(i\nabla + A_0)Z_a^R|^2 dx - \int_{D_R} |(i\nabla + A_{\mathbf{p}})\tilde{\varphi}_a|^2 dx \right) + (\lambda_a - \lambda_0) \\ &= o(\sqrt{H_{a, \delta}}), \end{aligned}$$

as $a = |a|\mathbf{p} \rightarrow 0$, thus concluding the proof. \square

From Theorem 3.5 and scaling, it follows that, letting $\alpha \in [0, 2\pi)$, $\mathbf{p} = (\cos \alpha, \sin \alpha)$, and $R > 1$,

$$(49) \quad \int_{\left(\frac{1}{|a|}\Omega\right) \setminus D_R} \left| (i\nabla + A_{\mathbf{p}}) \left(\tilde{\varphi}_a(x) - e^{\frac{i}{2}(\theta_{\mathbf{p}} - \theta_0^{\mathbf{p}})} \frac{|a|^{k/2}}{\sqrt{H_{a, \delta}}} W_a \right) \right|^2 dx = O(1), \quad \text{as } a = |a|\mathbf{p} \rightarrow 0.$$

Theorem 3.6. *For $\alpha \in [0, 2\pi)$, $\mathbf{p} = (\cos \alpha, \sin \alpha)$ and $a = |a|\mathbf{p} \in \Omega$, let $\varphi_a \in H_0^{1,a}(\Omega, \mathbb{C})$ solve (19-20) and $\varphi_0 \in H_0^{1,0}(\Omega, \mathbb{C})$ be a solution to (3) satisfying (1), (4), and (13). Let $\tilde{\varphi}_a$ and K_{δ} be as in (42), β_2 as in (5), and $\Psi_{\mathbf{p}}$ be as in Proposition 2.1. Then*

$$(50) \quad \lim_{|a| \rightarrow 0^+} \frac{|a|^{k/2}}{\sqrt{H_{a, \delta}}} = \frac{\sqrt{\pi}}{|\beta_2|} \sqrt{\frac{K_{\delta}}{\int_{\partial D_{K_{\delta}}} |\Psi_{\mathbf{p}}|^2 ds}}$$

and

$$(51) \quad \tilde{\varphi}_a \rightarrow \frac{\beta_2}{|\beta_2|} \sqrt{\frac{K_\delta}{\int_{\partial D_{K_\delta}} |\Psi_{\mathbf{p}}|^2 ds}} \Psi_{\mathbf{p}} \quad \text{as } a = |a|\mathbf{p} \rightarrow 0,$$

in $H^{1,\mathbf{p}}(D_R, \mathbb{C})$ for every $R > 1$, almost everywhere and in $C_{\text{loc}}^2(\mathbb{R}^2 \setminus \{\mathbf{p}\}, \mathbb{C})$.

Proof. Step 1. We first prove that for every sequence $a_n = |a_n|\mathbf{p}$ with $|a_n| \rightarrow 0$, there exist $\tilde{\Phi} \in H_{\text{loc}}^{1,\mathbf{p}}(\mathbb{R}^2, \mathbb{C})$, $\tilde{\Phi} \not\equiv 0$, and a subsequence a_{n_ℓ} such that $\tilde{\varphi}_{a_{n_\ell}} \rightarrow \tilde{\Phi}$ in $H^{1,\mathbf{p}}(D_R, \mathbb{C})$ for every $R > 1$, almost everywhere and in $C_{\text{loc}}^2(\mathbb{R}^2 \setminus \{\mathbf{p}\}, \mathbb{C})$ and $\tilde{\Phi}$ weakly solves

$$(52) \quad (i\nabla + A_{\mathbf{p}})^2 \tilde{\Phi} = 0, \quad \text{in } \mathbb{R}^2.$$

To prove it, we observe that from (41) it follows that, for every sequence $a_n = |a_n|\mathbf{p}$ with $|a_n| \rightarrow 0$, by a diagonal process there exists $\tilde{\Phi} \in H_{\text{loc}}^{1,\mathbf{p}}(\mathbb{R}^2, \mathbb{C})$, and a subsequence a_{n_ℓ} such that $\tilde{\varphi}_{a_{n_\ell}} \rightharpoonup \tilde{\Phi}$ weakly in $H^{1,\mathbf{p}}(D_R, \mathbb{C})$ for every $R > 1$ and almost everywhere. $\tilde{\Phi} \not\equiv 0$ since $\frac{1}{K_\delta} \int_{\partial D_{K_\delta}} |\tilde{\Phi}|^2 ds = 1$ thanks to (46) and the compactness of the trace embedding $H^{1,\mathbf{p}}(D_{K_\delta}, \mathbb{C}) \hookrightarrow L^2(\partial D_{K_\delta}, \mathbb{C})$.

Passing to the limit in (45), we have that $\tilde{\Phi}$ weakly solves (52), whereas, arguing as in the proof of [1, Theorem 8.1], we can prove that the convergence of the subsequence $\tilde{\varphi}_{a_{n_\ell}}$ to $\tilde{\Phi}$ is actually strong in $H^{1,\mathbf{p}}(D_R, \mathbb{C})$ for every $R > 1$. The convergence in $C_{\text{loc}}^2(\mathbb{R}^2 \setminus \{\mathbf{p}\}, \mathbb{C})$ follows easily from classical elliptic estimates.

Step 2. We claim that, for every sequence $a_n = |a_n|\mathbf{p}$ with $|a_n| \rightarrow 0$, there exists a subsequence a_{n_ℓ} such that

$$\lim_{\ell \rightarrow +\infty} \frac{|a_{n_\ell}|^{k/2}}{\sqrt{H_{a_{n_\ell}, \delta}}} \quad \text{is finite and strictly positive.}$$

To prove the claim, we argue by contradiction, assuming that

- (i) either there exists a sequence $a_n = |a_n|\mathbf{p}$ with $|a_n| \rightarrow 0$ such that $\lim_{n \rightarrow +\infty} \frac{|a_n|^{k/2}}{\sqrt{H_{a_n, \delta}}} = 0$
- (ii) or there exists a sequence $a_n = |a_n|\mathbf{p}$ with $|a_n| \rightarrow 0$ such that $\lim_{n \rightarrow +\infty} \frac{|a_n|^{k/2}}{\sqrt{H_{a_n, \delta}}} = +\infty$.

If (i) holds, then, by step 1, along a subsequence, $\tilde{\varphi}_{a_{n_\ell}} \rightarrow \tilde{\Phi}$ in $H^{1,\mathbf{p}}(D_R, \mathbb{C})$ for every $R > 1$, for some $\tilde{\Phi} \not\equiv 0$ weakly solving (52). Then from (30), passing to the limit in (49) we would obtain that

$$\int_{\mathbb{R}^2 \setminus D_R} |(i\nabla + A_{\mathbf{p}})\tilde{\Phi}(x)|^2 dx < +\infty,$$

contradicting the fact that $\tilde{\Phi} \not\equiv 0$ is a non trivial weak solution to (52) (and so cannot have finite energy otherwise by testing the equation we would get that $\tilde{\Phi} \equiv 0$, see [1, Proof of Proposition 4.3]). Hence case (i) cannot occur.

If (ii) holds, then from (49) we would have, for all $R > 2$

$$\frac{|a|^k}{H_{a, \delta}} \int_{D_{2R} \setminus D_R} \left| (i\nabla + A_{\mathbf{p}}) \left(\frac{\sqrt{H_{a, \delta}}}{|a|^{k/2}} \tilde{\varphi}_a(x) - e^{\frac{i}{2}(\theta_{\mathbf{p}} - \theta_{\mathbf{0}}^{\mathbf{p}})} W_a \right) \right|^2 dx = O(1), \quad \text{as } a = |a|\mathbf{p} \rightarrow 0,$$

and hence, in view of (30) and (41), passing to the limit along the sequence we would obtain that

$$\begin{aligned} & \frac{|a_n|^k}{H_{a_n, \delta}} \left(\int_{D_{2R} \setminus D_R} \left| (i\nabla + A_{\mathbf{p}}) \left(e^{\frac{i}{2}(\theta_{\mathbf{p}} - \theta_0^{\mathbf{p}})} \beta e^{\frac{i}{2}\theta_0} \psi_k \right) \right|^2 dx + o(1) \right) \\ &= \frac{|a_n|^k}{H_{a_n, \delta}} \left(|\beta|^2 \int_{D_{2R} \setminus D_R} |\nabla \psi_k|^2 dx + o(1) \right) = O(1), \quad \text{as } n \rightarrow +\infty, \end{aligned}$$

which is not possible if $\lim_{\ell \rightarrow +\infty} \frac{|a_{n_\ell}|^{k/2}}{\sqrt{H_{a_{n_\ell}, \delta}}} = +\infty$ as in case (ii), since $\int_{D_{2R} \setminus D_R} |\nabla \psi_k|^2 dx > 0$. Hence also case (ii) cannot occur and the claim of step 2 is proved.

Step 3. From steps 1 and 2, it follows that, for every sequence $a_n = (|a_n|, 0) = |a_n| \mathbf{p}$ with $|a_n| \rightarrow 0$, there exist $c \in (0, +\infty)$, $\tilde{\Phi} \in H_{\text{loc}}^{1, \mathbf{e}}(\mathbb{R}^2, \mathbb{C})$ weakly solving (52), $\tilde{\Phi} \neq 0$, and a subsequence a_{n_ℓ} such that $\lim_{\ell \rightarrow +\infty} \frac{|a_{n_\ell}|^{k/2}}{\sqrt{H_{a_{n_\ell}, \delta}}} = c$ and $\tilde{\varphi}_{a_{n_\ell}} \rightarrow \tilde{\Phi}$ in $H^{1, \mathbf{p}}(D_R, \mathbb{C})$ for every $R > 1$ and in $C_{\text{loc}}^2(\mathbb{R}^2 \setminus \{\mathbf{p}\}, \mathbb{C})$. Passing to the limit along a_{n_ℓ} in (49) and recalling (30), we obtain that, for every $R > 2$,

$$\int_{\mathbb{R}^2 \setminus D_R} \left| (i\nabla + A_{\mathbf{p}}) \left(\tilde{\Phi}(x) - c\beta e^{\frac{i}{2}(\theta_{\mathbf{p}} - \theta_0^{\mathbf{p}})} e^{\frac{i}{2}\theta_0} \psi_k \right) \right|^2 dx < +\infty,$$

where β is defined in (31). Hence from Proposition 2.1 we conclude that necessarily

$$(53) \quad \tilde{\Phi} = c\beta \Psi_{\mathbf{p}}.$$

Since $\frac{1}{K_\delta} \int_{\partial D_{K_\delta}} |\tilde{\Phi}|^2 ds = 1$, from (53) and the fact that c is a positive real number, it follows that $c = \frac{1}{|\beta|} \left(\frac{K_\delta}{\int_{\partial D_{K_\delta}} |\Psi_{\mathbf{p}}|^2 ds} \right)^{1/2}$. Hence we have that

$$\tilde{\varphi}_{a_{n_\ell}} \rightarrow \frac{\beta}{|\beta|} \sqrt{\frac{K_\delta}{\int_{\partial D_{K_\delta}} |\Psi_{\mathbf{p}}|^2 ds}} \Psi_{\mathbf{p}} \quad \text{in } H^{1, \mathbf{p}}(D_R, \mathbb{C}) \text{ for every } R > 1 \text{ and in } C_{\text{loc}}^2(\mathbb{R}^2 \setminus \{\mathbf{p}\}, \mathbb{C}),$$

and

$$\frac{|a_{n_\ell}|^{k/2}}{\sqrt{H_{a_{n_\ell}, \delta}}} \rightarrow \frac{1}{|\beta|} \sqrt{\frac{K_\delta}{\int_{\partial D_{K_\delta}} |\Psi_{\mathbf{p}}|^2 ds}}.$$

Since the above limits depend neither on the sequence $\{a_n\}_n$ nor on the subsequence $\{a_{n_\ell}\}_\ell$, we conclude that the above convergences hold as $|a| \rightarrow 0^+$, thus proving (50) and (51). \square

Remark 3.7. Combining (50) and (51) we deduce that

$$\frac{\varphi_a(|a|x)}{|a|^{k/2}} \rightarrow \frac{\beta_2}{\sqrt{\pi}} \Psi_{\mathbf{p}} \quad \text{as } a = |a| \mathbf{p} \rightarrow 0,$$

in $H^{1, \mathbf{p}}(D_R, \mathbb{C})$ for every $R > 1$ and in $C_{\text{loc}}^2(\mathbb{R}^2 \setminus \{\mathbf{p}\}, \mathbb{C})$. Furthermore, arguing as in [1, Lemma 8.3], from Theorem 3.6 we can deduce that, letting Z_a^R as is (47),

$$Z_a^R \rightarrow \frac{\beta_2}{|\beta_2|} \sqrt{\frac{K_\delta}{\int_{\partial D_{K_\delta}} |\Psi_{\mathbf{p}}|^2 ds}} z_R \quad \text{as } a = |a| \mathbf{p} \rightarrow 0,$$

in $H^{1,0}(D_R, \mathbb{C})$ for every $R > 2$, where z_R is the unique solution to

$$\begin{cases} (i\nabla + A_0)^2 z_R = 0, & \text{in } D_R, \\ z_R = e^{\frac{i}{2}(\theta_0^{\mathbf{p}} - \theta_{\mathbf{p}})} \Psi_{\mathbf{p}}, & \text{on } \partial D_R. \end{cases}$$

Thanks to the convergences of blow-up sequences established in Theorem 3.6 and Remark 3.7, we can now follow closely the arguments of [1, Subsection 6.1, Lemma 9.1] thus obtaining the following upper bound for the difference $\lambda_0 - \lambda_a$.

Lemma 3.8. *For $\alpha \in [0, 2\pi)$ and $a = |a|(\cos \alpha, \sin \alpha) \in \Omega$, let $\lambda_a \in \mathbb{R}$ and $\varphi_a \in H_0^{1,a}(\Omega, \mathbb{C})$ solve (19-20) and $\lambda_0 \in \mathbb{R}$ and $\varphi_0 \in H_0^{1,0}(\Omega, \mathbb{C})$ solve (3). If (1) and (4) hold and (13) is satisfied, then, for $a = |a|(\cos \alpha, \sin \alpha)$ and $\mathbf{p} = (\cos \alpha, \sin \alpha)$,*

$$\limsup_{|a| \rightarrow 0} \frac{\lambda_0 - \lambda_a}{|a|^k} \leq |\beta|^2 k\sqrt{\pi}(\xi_{\mathbf{p}}(1) - \sqrt{\pi}),$$

with β as in (31) and $\xi_{\mathbf{p}}(r)$ as defined in (35).

Collecting (38) and Lemma 3.8 we can state the following result.

Proposition 3.9. *For $\alpha \in [0, 2\pi)$ and $a = |a|(\cos \alpha, \sin \alpha) \in \Omega$, let $\varphi_a \in H_0^{1,a}(\Omega, \mathbb{C})$ and $\lambda_a \in \mathbb{R}$ solve (19-20) and $\lambda_0 \in \mathbb{R}$ and $\varphi_0 \in H_0^{1,0}(\Omega, \mathbb{C})$ solve (3). If (1) and (4) hold and (13) is satisfied, then, for $a = |a|(\cos \alpha, \sin \alpha)$,*

$$\lim_{|a| \rightarrow 0} \frac{\lambda_0 - \lambda_a}{|a|^k} = |\beta|^2 k\sqrt{\pi}f(\alpha),$$

where

$$(54) \quad f : [0, 2\pi) \rightarrow \mathbb{R}, \quad f(\alpha) = (\xi_{\mathbf{p}}(1) - \sqrt{\pi}), \quad \mathbf{p} = (\cos \alpha, \sin \alpha),$$

with β as in (31) and $\xi_{\mathbf{p}}(r)$ as defined in (35).

4. PROPERTIES OF $f(\alpha)$

To prove our main result, we are going to investigate two suitable symmetry properties of the function $f(\alpha)$. Let us define two transformations $\mathcal{R}_1, \mathcal{R}_2$ acting on a general point

$$x = (x_1, x_2) = (r \cos t, r \sin t), \quad r > 0, \quad t \in [0, 2\pi),$$

as

$$(55) \quad \mathcal{R}_1(x) = \mathcal{R}_1(x_1, x_2) = M_k \begin{pmatrix} x_1 \\ x_2 \end{pmatrix}, \quad M_k = \begin{pmatrix} \cos \frac{2\pi}{k} & -\sin \frac{2\pi}{k} \\ \sin \frac{2\pi}{k} & \cos \frac{2\pi}{k} \end{pmatrix}$$

i.e.

$$\mathcal{R}_1(r \cos t, r \sin t) = \left(r \cos\left(t + \frac{2\pi}{k}\right), r \sin\left(t + \frac{2\pi}{k}\right) \right),$$

and

$$(56) \quad \mathcal{R}_2(x) = \mathcal{R}_2(x_1, x_2) = (x_1, -x_2),$$

i.e.

$$\mathcal{R}_2(r \cos t, r \sin t) = (r \cos(2\pi - t), r \sin(2\pi - t)),$$

The transformation \mathcal{R}_1 is a rotation of $\frac{2\pi}{k}$ and \mathcal{R}_2 is a reflexion through the x_1 -axis.

We would like to study how the coefficient $\xi_{\mathbf{p}}(1)$ (see (35)) changes when the above transformations act on \mathbf{p} . In particular, we are going to prove that such a quantity $\xi_{\mathbf{p}}(1)$ is invariant under the transformations $\mathcal{R}_1, \mathcal{R}_2$.

In order to obtain such an invariance, we first study the relation between the limit profiles $\Psi_{\mathbf{p}}(\mathcal{R}_j(x))$ and $\Psi_{\mathcal{R}_j^{-1}(\mathbf{p})}(x)$, $j = 1, 2$.

Lemma 4.1. *For $\mathbf{p} = (\cos \alpha, \sin \alpha)$, $\alpha \in [0, 2\pi)$, let $\Psi_{\mathbf{p}}$ be the limit profile introduced in Proposition 2.1 and let $\mathcal{R}_1, \mathcal{R}_2$ be the transformations introduced in (55) and (56). Then*

$$(57) \quad \Psi_{\mathcal{R}_1^{-1}(\mathbf{p})} = -e^{-i\frac{\pi}{k}}(\Psi_{\mathbf{p}} \circ \mathcal{R}_1)$$

and

$$(58) \quad \Psi_{\mathcal{R}_2(\mathbf{p})} = -e^{i\theta_{\mathcal{R}_2(\mathbf{p})}}(\Psi_{\mathbf{p}} \circ \mathcal{R}_2).$$

Proof. In order to prove (57), we observe that, by direct calculations,

$$(59) \quad (A_{\mathbf{p}} \circ \mathcal{R}_1)(x) = A_{\mathcal{R}_1^{-1}(\mathbf{p})}(x)M_k^{-1},$$

$$(60) \quad e^{\frac{i}{2}(\theta_0 \circ \mathcal{R}_1)}(\psi_k \circ \mathcal{R}_1) = -e^{i\frac{\pi}{k}}e^{\frac{i}{2}\theta_0}\psi_k,$$

$$(61) \quad e^{\frac{i}{2}(\theta_0 \circ \mathcal{R}_1)(x)}\nabla\psi_k(\mathcal{R}_1(x)) = -e^{i\frac{\pi}{k}}e^{\frac{i}{2}\theta_0(x)}\nabla\psi_k(x)M_k^{-1}.$$

Furthermore

$$\theta_{\mathbf{p}}(\mathcal{R}_1(x)) = \begin{cases} \theta_{\mathcal{R}_1^{-1}(\mathbf{p})}(x) + \frac{2\pi}{k}, & \text{if } \alpha \in [\frac{2\pi}{k}, 2\pi), \\ \theta_{\mathcal{R}_1^{-1}(\mathbf{p})}(x) + \frac{2\pi}{k} - 2\pi, & \text{if } \alpha \in [0, \frac{2\pi}{k}), \end{cases}$$

and

$$\theta_0^{\mathbf{p}}(\mathcal{R}_1(x)) = \begin{cases} \theta_0^{\mathcal{R}_1^{-1}(\mathbf{p})}(x) + \frac{2\pi}{k}, & \text{if } \alpha \in [\frac{2\pi}{k}, 2\pi), \\ \theta_0^{\mathcal{R}_1^{-1}(\mathbf{p})}(x) + \frac{2\pi}{k} - 2\pi, & \text{if } \alpha \in [0, \frac{2\pi}{k}), \end{cases}$$

so that

$$(62) \quad \theta_{\mathcal{R}_1^{-1}(\mathbf{p})} - \theta_0^{\mathcal{R}_1^{-1}(\mathbf{p})} = \theta_{\mathbf{p}} \circ \mathcal{R}_1 - \theta_0^{\mathbf{p}} \circ \mathcal{R}_1.$$

Let us denote $\tilde{\Psi}_{\mathbf{p}}(y) = \Psi_{\mathbf{p}}(\mathcal{R}_1(y))$. By direct calculations we have that, since $\Psi_{\mathbf{p}}$ weakly solves the equation $(i\nabla + A_{\mathbf{p}})^2\Psi_{\mathbf{p}} = 0$, the function $\tilde{\Psi}_{\mathbf{p}}$ solves $(i\nabla + (A_{\mathbf{p}} \circ \mathcal{R}_1)M_k)^2\tilde{\Psi}_{\mathbf{p}} = 0$ and hence, in view of (59),

$$(63) \quad (i\nabla + A_{\mathcal{R}_1^{-1}(\mathbf{p})})^2\tilde{\Psi}_{\mathbf{p}} = 0, \quad \text{in } \mathbb{R}^2 \text{ in a weak } H^{1, \mathcal{R}_1^{-1}(\mathbf{p})}\text{-sense.}$$

Passing to the limit in (49) and taking into account (30) and Theorem 3.6, we obtain that, for all $R > 1$,

$$(64) \quad \int_{\mathbb{R}^2 \setminus D_R} \left| (i\nabla + A_{\mathbf{p}}) \left(\Psi_{\mathbf{p}} - e^{\frac{i}{2}(\theta_{\mathbf{p}} - \theta_0^{\mathbf{p}} + \theta_0)}\psi_k \right) \right|^2 dx \\ = \int_{\mathbb{R}^2 \setminus D_R} \left| (i\nabla + A_{\mathbf{p}})\Psi_{\mathbf{p}} - e^{\frac{i}{2}(\theta_{\mathbf{p}} - \theta_0^{\mathbf{p}} + \theta_0)}i\nabla\psi_k \right|^2 dx < +\infty.$$

By the change of variable $x = \mathcal{R}_1(y)$ in the above integral, using (59), (61), and (62) we obtain that

$$\begin{aligned}
(65) \quad & \int_{\mathbb{R}^2 \setminus D_R} \left| (i\nabla + A_{\mathbf{p}})\Psi_{\mathbf{p}}(x) - e^{\frac{i}{2}(\theta_{\mathbf{p}} - \theta_0^{\mathbf{p}} + \theta_0)(x)} i\nabla \psi_k(x) \right|^2 dx \\
&= \int_{\mathbb{R}^2 \setminus D_R} \left| (i\nabla + A_{\mathcal{R}_1^{-1}(\mathbf{p})})\tilde{\Psi}_{\mathbf{p}}(y) + e^{\frac{i}{k}\pi} e^{\frac{i}{2}(\theta_{\mathcal{R}_1^{-1}(\mathbf{p})} - \theta_0^{\mathcal{R}_1^{-1}(\mathbf{p})} + \theta_0)(y)} i\nabla \psi_k(y) \right|^2 dy \\
&= \int_{\mathbb{R}^2 \setminus D_R} \left| (i\nabla + A_{\mathcal{R}_1^{-1}(\mathbf{p})})(-e^{-\frac{i}{k}\pi}\tilde{\Psi}_{\mathbf{p}})(y) - e^{\frac{i}{2}(\theta_{\mathcal{R}_1^{-1}(\mathbf{p})} - \theta_0^{\mathcal{R}_1^{-1}(\mathbf{p})} + \theta_0)(y)} i\nabla \psi_k(y) \right|^2 dy < +\infty.
\end{aligned}$$

From (63), (65) and Proposition 2.1 we conclude that

$$-e^{-\frac{i}{k}\pi}\tilde{\Psi}_{\mathbf{p}} = \Psi_{\mathcal{R}_1^{-1}(\mathbf{p})}$$

thus proving (57).

To prove (58), we first observe that direct calculations yield

$$(66) \quad (A_{\mathcal{R}_2(\mathbf{p})} \circ \mathcal{R}_2)M^{-1} = -A_{\mathbf{p}}, \quad \text{where } M = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix},$$

$$(67) \quad \psi_k \circ \mathcal{R}_2 = \psi_k, \quad \nabla \psi_k(\mathcal{R}_2(x)) = \nabla \psi_k(x)M^{-1}.$$

Moreover

$$\begin{aligned}
\theta_{\mathbf{p}}(\mathcal{R}_2(x)) &= \begin{cases} 4\pi - \theta_{\mathcal{R}_2(\mathbf{p})}(x), & \text{if } \theta_{\mathbf{p}}(\mathcal{R}_2(x)) \in (\alpha, \alpha + 2\pi), \\ 2\pi - \theta_{\mathcal{R}_2(\mathbf{p})}(x), & \text{if } \theta_{\mathbf{p}}(\mathcal{R}_2(x)) = \alpha, \end{cases} \quad \text{if } \alpha \in (0, 2\pi), \\
\theta_{\mathbf{p}}(\mathcal{R}_2(x)) &= \begin{cases} 2\pi - \theta_{\mathcal{R}_2(\mathbf{p})}(x) = 2\pi - \theta_{\mathbf{p}}(x), & \text{if } \theta_{\mathbf{p}}(\mathcal{R}_2(x)) \in (0, 2\pi), \\ -\theta_{\mathcal{R}_2(\mathbf{p})}(x) = 0, & \text{if } \theta_{\mathbf{p}}(\mathcal{R}_2(x)) = 0, \end{cases} \quad \text{if } \alpha = 0,
\end{aligned}$$

and

$$\begin{aligned}
\theta_0^{\mathbf{p}}(\mathcal{R}_2(x)) &= \begin{cases} 4\pi - \theta_0^{\mathcal{R}_2(\mathbf{p})}(x), & \text{if } \theta_0^{\mathbf{p}}(\mathcal{R}_2(x)) \in (\alpha, \alpha + 2\pi), \\ 2\pi - \theta_0^{\mathcal{R}_2(\mathbf{p})}(x), & \text{if } \theta_0^{\mathbf{p}}(\mathcal{R}_2(x)) = \alpha, \end{cases} \quad \text{if } \alpha \in (0, 2\pi), \\
\theta_0^{\mathbf{p}}(\mathcal{R}_2(x)) = \theta_0(\mathcal{R}_2(x)) &= \begin{cases} 2\pi - \theta_0(x), & \text{if } \theta_0(x) \in (0, 2\pi), \\ -\theta_0(x) = 0, & \text{if } \theta_0(x) = 0, \end{cases} \quad \text{if } \alpha = 0,
\end{aligned}$$

so that

$$(68) \quad \theta_0^{\mathcal{R}_2(\mathbf{p})} - \theta_{\mathcal{R}_2(\mathbf{p})} = \theta_{\mathbf{p}} \circ \mathcal{R}_2 - \theta_0^{\mathbf{p}} \circ \mathcal{R}_2, \quad \text{in } \mathbb{R}^2 \setminus \{t\mathbf{p} : t \in [0, 1]\},$$

and

$$(69) \quad e^{\frac{i}{2}\theta_0(\mathcal{R}_2(y))} = -e^{-\frac{i}{2}\theta_0(y)}, \quad \text{in } \mathbb{R}^2 \setminus \{(x_1, 0) : x_1 \geq 0\}.$$

Let us denote $\widehat{\Psi}_{\mathbf{p}}(y) = -e^{i\theta_{\mathcal{R}_2(\mathbf{p})}}\Psi_{\mathbf{p}}(\mathcal{R}_2(y))$. In view of (66), it is easy to verify that $\widehat{\Psi}_{\mathbf{p}}$ solves

$$(70) \quad (i\nabla + A_{\mathcal{R}_2(\mathbf{p})})^2 \widehat{\Psi}_{\mathbf{p}} = 0, \quad \text{in } \mathbb{R}^2 \text{ in a weak } H^{1, \mathcal{R}_2(\mathbf{p})}\text{-sense.}$$

By the change of variable $x = \mathcal{R}_2(y)$ in the integral (64), using (66), (67), (68), and (69) and observing that, by (18), $e^{-i(\theta_0^{\mathcal{R}_2(\mathbf{p})} - \theta_0)} \equiv 1$ in $\mathbb{R}^2 \setminus D_R$,

we obtain that

$$\begin{aligned}
(71) \quad & \int_{\mathbb{R}^2 \setminus D_R} \left| (i\nabla + A_{\mathbf{p}})\Psi_{\mathbf{p}}(x) - e^{\frac{i}{2}(\theta_{\mathbf{p}} - \theta_0^{\mathbf{p}} + \theta_0)(x)} i\nabla \psi_k(x) \right|^2 dx \\
&= \int_{\mathbb{R}^2 \setminus D_R} \left| (i\nabla + (A_{\mathbf{p}} \circ \mathcal{R}_2)M)(-\Psi_{\mathbf{p}} \circ \mathcal{R}_2)(y) - e^{-\frac{i}{2}(\theta_{\mathcal{R}_2(\mathbf{p})} - \theta_0^{\mathcal{R}_2(\mathbf{p})} + \theta_0)(y)} i\nabla \psi_k(y) \right|^2 dy \\
&= \int_{\mathbb{R}^2 \setminus D_R} \left| (i\nabla - A_{\mathcal{R}_2(\mathbf{p})})(-\Psi_{\mathbf{p}} \circ \mathcal{R}_2)(y) - e^{-\frac{i}{2}(\theta_{\mathcal{R}_2(\mathbf{p})} - \theta_0^{\mathcal{R}_2(\mathbf{p})} + \theta_0)(y)} i\nabla \psi_k(y) \right|^2 dy \\
&= \int_{\mathbb{R}^2 \setminus D_R} \left| e^{i(\theta_{\mathcal{R}_2(\mathbf{p})} - \theta_0^{\mathcal{R}_2(\mathbf{p})} + \theta_0)} (i\nabla - A_{\mathcal{R}_2(\mathbf{p})})(-\Psi_{\mathbf{p}} \circ \mathcal{R}_2) - e^{\frac{i}{2}(\theta_{\mathcal{R}_2(\mathbf{p})} - \theta_0^{\mathcal{R}_2(\mathbf{p})} + \theta_0)} i\nabla \psi_k \right|^2 dy \\
&= \int_{\mathbb{R}^2 \setminus D_R} \left| e^{i\theta_{\mathcal{R}_2(\mathbf{p})}} (i\nabla - A_{\mathcal{R}_2(\mathbf{p})})(-\Psi_{\mathbf{p}} \circ \mathcal{R}_2) - e^{\frac{i}{2}(\theta_{\mathcal{R}_2(\mathbf{p})} - \theta_0^{\mathcal{R}_2(\mathbf{p})} + \theta_0)} i\nabla \psi_k \right|^2 dy \\
&= \int_{\mathbb{R}^2 \setminus D_R} \left| (i\nabla + A_{\mathcal{R}_2(\mathbf{p})})\widehat{\Psi}_{\mathbf{p}} - e^{\frac{i}{2}(\theta_{\mathcal{R}_2(\mathbf{p})} - \theta_0^{\mathcal{R}_2(\mathbf{p})} + \theta_0)} i\nabla \psi_k \right|^2 dy.
\end{aligned}$$

From (70), (71) and Proposition 2.1 we conclude that

$$\widehat{\Psi}_{\mathbf{p}} = \Psi_{\mathcal{R}_2(\mathbf{p})}$$

thus proving (58). \square

We are now in position to prove invariance properties of the function $\mathbf{p} \mapsto \xi_{\mathbf{p}}(1)$ under the transformations (55) and (56).

Lemma 4.2. *Let $\mathcal{R}_1, \mathcal{R}_2$ be the transformations introduced in (55)-(56), $\alpha \in [0, 2\pi)$, and $\mathbf{p} = (\cos \alpha, \sin \alpha)$. Then*

$$(72) \quad \xi_{\mathcal{R}_1^{-1}(\mathbf{p})}(1) = \xi_{\mathbf{p}}(1)$$

and

$$(73) \quad \xi_{\mathcal{R}_2(\mathbf{p})}(1) = \xi_{\mathbf{p}}(1),$$

where $\xi_{\mathbf{p}}$ is defined in (35).

Proof. We first notice that, from (14),

$$(74) \quad \psi_2^k\left(s + \frac{2\pi}{k}\right) = -e^{i\frac{\pi}{k}} \psi_2^k(s), \quad \text{for all } s \in \mathbb{R},$$

and

$$(75) \quad \psi_2^k(2\pi - s) = -e^{-is} \psi_2^k(s), \quad \text{for all } s \in \mathbb{R}.$$

By the change of variable $t = s + \frac{2\pi}{k}$ in the integral defining $\xi_{\mathbf{p}}(1)$, from (74), (62) and (57) we obtain that

$$\begin{aligned}\xi_{\mathbf{p}}(1) &= \int_0^{2\pi} e^{-\frac{i}{2}(\theta_{\mathbf{p}} - \theta_0^{\mathbf{p}})(\cos t, \sin t)} \Psi_{\mathbf{p}}(\cos t, \sin t) \overline{\psi_2^k(t)} dt \\ &= -e^{-i\frac{\pi}{k}} \int_0^{2\pi} e^{-\frac{i}{2}(\theta_{\mathbf{p}} - \theta_0^{\mathbf{p}})(\mathcal{R}_1(\cos s, \sin s))} \Psi_{\mathbf{p}}(\mathcal{R}_1(\cos s, \sin s)) \overline{\psi_2^k(s)} ds \\ &= \int_0^{2\pi} e^{-\frac{i}{2}(\theta_{\mathcal{R}_1^{-1}(\mathbf{p})} - \theta_0^{\mathcal{R}_1^{-1}(\mathbf{p})})(\cos s, \sin s)} \Psi_{\mathcal{R}_1^{-1}(\mathbf{p})}(\cos s, \sin s) \overline{\psi_2^k(s)} ds \\ &= \xi_{\mathcal{R}_1^{-1}(\mathbf{p})}(1),\end{aligned}$$

thus proving (72).

By the change of variable $t = 2\pi - s$ in the integral defining $\xi_{\mathbf{p}}(1)$, from (75), (68), (58), and (18) we obtain that

$$\begin{aligned}\xi_{\mathbf{p}}(1) &= \int_0^{2\pi} e^{-\frac{i}{2}(\theta_{\mathbf{p}} - \theta_0^{\mathbf{p}})(\cos t, \sin t)} \Psi_{\mathbf{p}}(\cos t, \sin t) \overline{\psi_2^k(t)} dt \\ &= - \int_0^{2\pi} e^{-\frac{i}{2}(\theta_{\mathbf{p}} - \theta_0^{\mathbf{p}})(\mathcal{R}_2(\cos s, \sin s))} \Psi_{\mathbf{p}}(\mathcal{R}_2(\cos s, \sin s)) e^{i\theta_0(\cos s, \sin s)} \overline{\psi_2^k(s)} ds \\ &= \int_0^{2\pi} e^{-\frac{i}{2}(\theta_0^{\mathcal{R}_2(\mathbf{p})} - \theta_{\mathcal{R}_2(\mathbf{p})})(\cos s, \sin s)} e^{-i\theta_{\mathcal{R}_2(\mathbf{p})}(\cos s, \sin s)} \Psi_{\mathcal{R}_2(\mathbf{p})}(\cos s, \sin s) e^{i\theta_0(\cos s, \sin s)} \overline{\psi_2^k(s)} ds \\ &= \int_0^{2\pi} e^{-\frac{i}{2}(\theta_{\mathcal{R}_2(\mathbf{p})} - \theta_0^{\mathcal{R}_2(\mathbf{p})})(\cos s, \sin s)} e^{-i(\theta_0^{\mathcal{R}_2(\mathbf{p})} - \theta_0)(\cos s, \sin s)} \Psi_{\mathcal{R}_2(\mathbf{p})}(\cos s, \sin s) \overline{\psi_2^k(s)} ds \\ &= \int_0^{2\pi} e^{-\frac{i}{2}(\theta_{\mathcal{R}_2(\mathbf{p})} - \theta_0^{\mathcal{R}_2(\mathbf{p})})(\cos s, \sin s)} \Psi_{\mathcal{R}_2(\mathbf{p})}(\cos s, \sin s) \overline{\psi_2^k(s)} ds \\ &= \xi_{\mathcal{R}_2(\mathbf{p})}(1),\end{aligned}$$

thus proving (73). □

Let f be the 2π -periodic extension of the function introduced in (54), i.e.

$$(76) \quad f(\alpha) = \xi_{(\cos \alpha, \sin \alpha)}(1) - \sqrt{\pi}, \quad \text{for all } \alpha \in \mathbb{R},$$

with $\xi_{\mathbf{p}}$ defined in (35).

Corollary 4.3. *Let f be defined in (76). Then*

$$f(\alpha) = f\left(\alpha - \frac{2\pi}{k}\right) \quad \text{and} \quad f(\alpha) = f(2\pi - \alpha)$$

for all $\alpha \in \mathbb{R}$.

Proof. It is a straightforward consequence of Lemma 4.2. □

5. PROOF OF THE MAIN RESULT

From Lemma 1.1 and Proposition 3.9, it follows that, under assumption (13), the homogeneous polynomial P (12) of degree k appearing in the expansion (11) is given by

$$(77) \quad P(r \cos \alpha, r \sin \alpha) = r^k |\beta|^2 k \sqrt{\pi} f(\alpha), \quad r > 0, \alpha \in \mathbb{R},$$

with f as in (76). Furthermore, from Corollary 4.3 and (77), we have that the 2π -periodic function

$$(78) \quad g : \mathbb{R} \rightarrow \mathbb{R}, \quad g(\alpha) := P(\cos \alpha, \sin \alpha) = \sum_{j=0}^k c_j (\cos \alpha)^{k-j} (\sin \alpha)^j$$

satisfy the periodicity/symmetry conditions

$$(79) \quad g(\alpha) = g\left(\alpha + \frac{2\pi}{k}\right) \quad \text{and} \quad g(\alpha) = g(2\pi - \alpha), \quad \text{for all } \alpha \in \mathbb{R}.$$

From [1, Theorem 1.2] we also know that

$$(80) \quad c_0 = g(0) = -4 \frac{|\beta_2|^2}{\pi} \mathbf{m}_k > 0,$$

with \mathbf{m}_k being as in (9)–(10) and β_2 as in (5).

Lemma 5.1. *Under the assumptions of Lemma 1.1 and (13), let P be as in (11)–(12) and g be defined in (78). Then*

$$g(\alpha) = \frac{c_0}{\prod_{\ell=1}^k \sin\left(\frac{\pi}{2k}(2\ell - 1)\right)} \prod_{j=1}^k \sin\left(\frac{\pi}{2k}(2j - 1) - \alpha\right), \quad \text{for all } \alpha \in \mathbb{R}.$$

Proof. From (80) and (79), we have that

$$(81) \quad g\left(j \frac{2\pi}{k}\right) > 0 \quad \text{for all } j = 0, 1, \dots, \frac{k-1}{2}.$$

Moreover, from (78) and oddness of k , we have that

$$(82) \quad g(\alpha + \pi) = -g(\alpha), \quad \text{for all } \alpha \in \mathbb{R},$$

and hence from (79) we deduce that

$$(83) \quad g\left(\frac{\pi}{k} + j \frac{2\pi}{k}\right) = g\left(\pi + \left(\frac{\pi}{k} - \pi + j \frac{2\pi}{k}\right)\right) \\ = g\left(\pi + \frac{2\pi}{k}\left(j + \frac{1-k}{2}\right)\right) = g(\pi) = -g(0) < 0 \quad \text{for all } j = 0, 1, \dots, \frac{k-1}{2}.$$

From (81) and (83) we infer that g has at least k distinct zeros $\theta_1, \theta_2, \dots, \theta_k$ in $(0, \pi)$ such that

$$(j-1) \frac{\pi}{k} < \theta_j < j \frac{\pi}{k}, \quad \text{for all } j = 1, \dots, k.$$

In view of this fact, we aim at factorizing the function g . For every $\alpha \in \mathbb{R} \setminus \{\ell\pi : \ell \in \mathbb{Z}\}$ we have that

$$(84) \quad g(\alpha) = (\sin \alpha)^k \tilde{P}(\cot \alpha)$$

where

$$\tilde{P}(t) = \sum_{j=0}^k c_j t^{k-j}.$$

From (80) the 1-variable polynomial \tilde{P} has degree k . Furthermore, by (84), $\cot \theta_1, \dots, \cot \theta_k$ are k distinct real zeroes of \tilde{P} . Therefore from the Fundamental Theorem of Algebra it follows

that $\tilde{P}(t) = c_0 \prod_{j=1}^k (t - \cot \theta_j)$, and hence, in view of (84),

$$\begin{aligned} g(\alpha) &= c_0 (\sin \alpha)^k \prod_{j=1}^k (\cot \alpha - \cot \theta_j) = c_0 \prod_{j=1}^k (\cos \alpha - \cot \theta_j \sin \alpha) \\ &= c_0 \prod_{j=1}^k \frac{1}{\sin \theta_j} (\sin \theta_j \cos \alpha - \cos \theta_j \sin \alpha) = c_0 \prod_{j=1}^k \frac{1}{\sin \theta_j} \sin(\theta_j - \alpha), \end{aligned}$$

for all $\alpha \in \mathbb{R} \setminus \{\ell\pi : \ell \in \mathbb{Z}\}$. Then, by continuity, we conclude that

$$(85) \quad g(\alpha) = c_0 \prod_{j=1}^k \frac{1}{\sin \theta_j} \sin(\theta_j - \alpha), \quad \text{for all } \alpha \in \mathbb{R}.$$

We notice that (85) implies that the values $\theta_1, \theta_2, \dots, \theta_k$ are the unique zeros of g in the interval $(0, \pi)$. In particular, for every $j \in \{1, \dots, k\}$,

$$(86) \quad \theta_j \text{ is the unique zero of } g \text{ in the interval } \left((j-1)\frac{\pi}{k}, j\frac{\pi}{k} \right).$$

From (79) and (82) we have that

$$\begin{aligned} &g\left(\theta_1 + (j-1)\frac{\pi}{k}\right) \\ &= \begin{cases} g(\theta_1), & \text{if } j \text{ is odd,} \\ -g(\theta_1 + \pi + (j-1)\frac{\pi}{k}) = -g(\theta_1 + (j-1+k)\frac{\pi}{k}) = -g(\theta_1), & \text{if } j \text{ is even,} \end{cases} \\ &= 0, \end{aligned}$$

and hence, in view of (86) and since $\theta_1 + (j-1)\frac{\pi}{k} \in \left((j-1)\frac{\pi}{k}, j\frac{\pi}{k} \right)$, we have that

$$(87) \quad \theta_j = \theta_1 + (j-1)\frac{\pi}{k}, \quad \text{for all } j = 1, \dots, k.$$

From (79) it follows that $g(-\theta_1 + \frac{2\pi}{k}) = g(-\theta_1) = g(2\pi - \theta_1) = g(\theta_1) = 0$; therefore, since $-\theta_1 + \frac{2\pi}{k} \in \left(\frac{\pi}{k}, \frac{2\pi}{k} \right)$, from (86) and (87) we can conclude that $-\theta_1 + \frac{2\pi}{k} = \theta_2 = \theta_1 + \frac{\pi}{k}$ and hence $\theta_1 = \frac{\pi}{2k}$. Then from (87) we deduce that

$$\theta_j = \frac{\pi}{2k}(2j-1), \quad \text{for all } j = 1, \dots, k,$$

thus reaching the conclusion in view of (85). \square

Lemma 5.2. *Let k be an odd natural number. Then*

$$\prod_{j=1}^k \sin\left(\frac{\pi}{2k}(2j-1) - \alpha\right) = 2^{1-k} \cos(k\alpha)$$

for all $\alpha \in \mathbb{R}$.

Proof. Since the complex numbers $e^{i\frac{2\pi}{k}j}$ with $j = 1, 2, \dots, k$ are k -th distinct roots of unity and k is odd, we have that

$$(88) \quad 1 - z^k = \prod_{j=1}^k \left(e^{i\frac{2\pi}{k}j} - z \right), \quad \text{for all } z \in \mathbb{C}.$$

Since

$$\begin{aligned} \sin\left(\frac{\pi}{2k}(2j-1)-\alpha\right) &= \frac{e^{i\left(\frac{\pi}{2k}(2j-1)-\alpha\right)} - e^{-i\left(\frac{\pi}{2k}(2j-1)-\alpha\right)}}{2i} \\ &= \frac{1}{2i} e^{-i\alpha} e^{-i\frac{\pi}{2k}(2j+1)} \left(e^{i\frac{2\pi}{k}j} - e^{i(2\alpha+\frac{\pi}{k})} \right) = \frac{1}{2} e^{-i\alpha} e^{-i\frac{\pi}{2k}(2j+1+k)} \left(e^{i\frac{2\pi}{k}j} - e^{i(2\alpha+\frac{\pi}{k})} \right), \end{aligned}$$

from (88) we deduce that

$$\begin{aligned} \prod_{j=1}^k \sin\left(\frac{\pi}{2k}(2j-1)-\alpha\right) &= \frac{1}{2^k} e^{-ik\alpha} e^{-i\frac{\pi}{k}\sum_{j=1}^k j} e^{-i\frac{\pi}{2}(1+k)} \prod_{j=1}^k \left(e^{i\frac{2\pi}{k}j} - e^{i(2\alpha+\frac{\pi}{k})} \right) \\ &= \frac{1}{2^k} e^{-ik\alpha} e^{-i\pi(1+k)} \left(1 - e^{i(2k\alpha+\pi)} \right) \\ &= \frac{1}{2^k} e^{-ik\alpha} \left(1 + e^{2ki\alpha} \right) = \frac{1}{2^k} \left(e^{-ik\alpha} + e^{ki\alpha} \right) = 2^{1-k} \cos(k\alpha) \end{aligned}$$

thus proving the lemma. \square

Proof of Theorem 1.2. From Lemmas 5.1 and 5.2 it follows that, under the assumptions of Lemma 1.1 and (13), the polynomial P in (11)-(12) is given by

$$P(r \cos \alpha, r \sin \alpha) = -4 \frac{|\beta_2|^2}{\pi} \mathbf{m}_k r^k \cos(k\alpha),$$

thus proving the conclusion in the case in which assumption (13) is satisfied. The general case $\beta_1 \neq 0$ can be easily reduced to the case $\beta_1 = 0$ by a change of the cartesian coordinate system (x_1, x_2) in \mathbb{R}^2 which rotates the axes in such a way that the positive x_1 -axis is tangent to one of the k nodal lines of φ_0 ending at 0. If $\beta_1 \neq 0$ and α_0 is defined in (6), the nodal lines of φ_0 at 0 have tangent half-lines forming with the x_1 -axis angles of $\alpha_0 + \frac{2\pi}{k}j$, $j = 0, 1, \dots, k-1$. If $\tilde{\varphi}_0(x) = \varphi_0(R(x))$ and $\tilde{\varphi}_a(x) = \varphi_a(R(x))$ with

$$R(x_1, x_2) = \begin{pmatrix} \cos \alpha_0 & -\sin \alpha_0 \\ \sin \alpha_0 & \cos \alpha_0 \end{pmatrix} \begin{pmatrix} x_1 \\ x_2 \end{pmatrix},$$

it is easy to verify that $\tilde{\varphi}_0, \tilde{\varphi}_a$ solve problems

$$(i\nabla + A_0)^2 \tilde{\varphi}_0 = \lambda_0 \tilde{\varphi}_0, \quad (i\nabla + A_{R^{-1}(a)})^2 \tilde{\varphi}_a = \lambda_a \tilde{\varphi}_a,$$

in the domain $R^{-1}(\Omega)$. Moreover

$$r^{-k/2} \tilde{\varphi}_0(r(\cos t, \sin t)) \rightarrow \tilde{\beta}_1 \frac{e^{i\frac{k}{2}t}}{\sqrt{\pi}} \cos\left(\frac{k}{2}t\right) + \tilde{\beta}_2 \frac{e^{i\frac{k}{2}t}}{\sqrt{\pi}} \sin\left(\frac{k}{2}t\right) \quad \text{in } C^{1,\tau}([0, 2\pi], \mathbb{C})$$

as $r \rightarrow 0^+$, where

$$\begin{pmatrix} \tilde{\beta}_1 \\ \tilde{\beta}_2 \end{pmatrix} = e^{i\frac{\alpha_0}{2}} \begin{pmatrix} \cos(\frac{k}{2}\alpha_0) & -\sin(\frac{k}{2}\alpha_0) \\ \sin(\frac{k}{2}\alpha_0) & \cos(\frac{k}{2}\alpha_0) \end{pmatrix} \begin{pmatrix} \beta_1 \\ \beta_2 \end{pmatrix}.$$

From (6) it follows that $\tilde{\beta}_1 = 0$ and hence $|\tilde{\beta}_2|^2 = |\beta_1|^2 + |\beta_2|^2$. Since we have already proved the theorem in the case $\beta_1 = 0$, we know that

$$\frac{\lambda_0 - \lambda_a}{|a|^k} \rightarrow -4 \frac{|\tilde{\beta}_2|^2}{\pi} \mathbf{m}_k \cos(k\alpha), \quad \text{as } a \rightarrow 0 \text{ with } R^{-1}(a) = |a|(\cos \alpha, \sin \alpha),$$

which yields

$$\frac{\lambda_0 - \lambda_a}{|a|^k} \rightarrow -4 \frac{|\beta_1|^2 + |\beta_2|^2}{\pi} \mathbf{m}_k \cos(k(\theta - \alpha_0)), \quad \text{as } a \rightarrow 0 \text{ with } a = |a|(\cos \theta, \sin \theta),$$

thus concluding the proof. \square
